Iraqi Journal of Medical Sciences

Aims and Scope

Iraqi Journal of Medical Sciences is published by College of Medicine, Al-Nahrain University. It is a quarterly multidisciplinary medical journal. High quality papers written in English, dealing with aspects of clinical, academic or investigative medicine or research will be welcomed. Emphasis is placed on matters relating to medicine in Iraq in particular and the Middle East in general, though articles are welcomed from anywhere in the world.

Iraqi Journal of Medical Sciences publishes original articles, case reports, and letters to the editor, editorials, investigative medicine, and review articles. They include forensic medicine, history of medicine, medical ethics, and religious aspects of medicine, and other selected topics.
Iraqi Journal of Medical Sciences (Iraqi JMS) is a periodic, peer-reviewed journal published quarterly by College of Medicine, Al-Nahrain University. Iraqi JMS publishes manuscripts in all fields of health and medicine written in English.

**Types of Contributions:** Original articles, review articles, case studies, editorials, medical education, history of medicine, ethics, practical points, medical quiz, conferences, meetings and letters to the Editor.

**Manuscripts:**
- Submission of a manuscript implies that it is not being considered for publication anywhere.
- The author should provide a document officially state that the current work was carried out at the site which provides this certification. The document should be signed by the highest authorized member at that location.
- Manuscripts submitted to IJMS are subject to editorial evaluation and revision by two referees.
- The format of IJMS complies with the uniform requirements for manuscripts submitted to Biomedical Journals, published by the International Committee of Medical Journals Editors (ICMJE) (Vancouver, British Colombia, 1979) and its last update in October 2001, available on the web site www.icmje.org.
- Manuscript should be typewritten double spaced on size A4 (29.5x21 cm) paper with wide margins. Page should be numbered consecutively. One original and two photocopies including figures, tables, and photographs should be submitted. Begin each of following sections on separate page in the following sequence: Title page, abstract and keywords, text, acknowledgments, references, tables, and legends for illustration.
- Manuscript and figures will not be returned to the authors whether the editorial decision is to accept, revise or reject.
- Manuscripts must be accompanied by a covering paper signed by all authors that the paper has not been published in and will not be submitted to any other journal if accepted in IJMS.
- The page should contain (a) title of the manuscript, (b) names of each author (first name, middle initial and family name) including highest academic degree, (c) official academic and/or clinical title and affiliation (d) name and address of the institution where the work was done (e) name and address (E-mail if available) of the author to whom correspondence should be sent.

**Abstract:** manuscript should include an abstract of not more than 150 words. Structured abstract typed on a separate sheet and consist of background, objective, method, results, and conclusion. Translation in Arabic to be included: ﻣﻼظة اﻟﺪراﺳﺔ، ﺗﻢ ﺟﺎری اﻟﺪراﺳﺔ، ﻣﺪاﻧﺔ اﻟﺪراﺳﺔ، ﻣﺎردة اﻟﺪراﺳﺎت، ﻣﺎزدة اﻟﺪراﺳﺎت، ﺟﺎردة اﻟﺪراﺳﺎت، ﻣﺎزدة اﻟﺪراﺳﺎت.

**Keywords:** three to ten keywords should be provided on the same page as the abstract in Arabic and English. As far as possible, be selected from the National Library of Medicine Medical Subject Headings.

The Arabic abstract should follow the United Medical Dictionary (Council of Arab Ministers of Health/WHO/ Arab Medical Union/ALESCO, 3rd edition.

**Manuscript format:** It should be divided into the following parts: introduction, materials and methods, results and discussion.
• **References:** All references should be listed in consecutive numerical order by English numerical, in the order of citation in the text. Once a reference is cited all subsequent citations should be to the original number.

**Examples**

• **Tables:** Each table should be typed on a separate page double-spaced, including all headings, number all tables with English numerals and include a short title. Vertical lines between columns are to be avoided.

• **Figures:** All figures must be suitable for reproduction without being retouched or redrawn. Figure number, name of senior author, and title of the work should be written lightly on the back with red pencil. Photographs must be supplied as glossy black and white prints. The top of the figures should be indicated clearly.

• **Legends:** Captions for figures must be typed; double spaced, and must not appear on the figure.

Proof Reading will be done by the secretarial office of the journal. The principal author will receive a copy of the journal. The authors are responsible for accuracy of all statements, data, and references included in the manuscript.

• After the manuscript has been accepted for publication, authors are required to supply the final version of the manuscript on 3.5” IBM-compatible floppy disk in MS word version 6 or later.

• All corresponding to be addressed to the Chief Editor on the address below:

ARABIC ABSTRACTS
EDITORIAL

GMC MEANS PEACE
Abdul Hussain M Al-Hadi PhD.

The global movement for mothers and children was declared in the late nineties and aims at improving the status of mothers and children all over the world with special emphasis on mothers and children in the developing world.

The WHO report for the year 2005 emphasizes that mothers and children matters so does their health.

In many countries universal access to the care all women and children are entitled still far from realization. This movement aims at meeting the principle requirements for child survival and mother revival.

It is necessary to refocus the technical strategies developed within maternal and child health programs and to put more emphasis on the importance for the often-overlooked health problems of newborn.

Management of child health has become one of the major programs developed to care for children from the under five group. It also aims to make such care more realistic and fruitful through upgrading the performance of health care workers to care for all health problems that are facing children feasibly and appropriately, at the same time the program give special importance to role that can be played by the family in providing care for the child who suffer from these problems.

Environmental sanitation has proven a major role in promotion, protection and maintenance of the health of general population, through ensuring safe water supply and safe environment free from pollution one can ensure good health and high developmental opportunities.

Women and girls need special attention throughout their developmental stages, they both are at high risk of wider range of health problems related to their physiological characteristics. Women need special care during pregnancy, childbirth, postpartum and even more attention to the newborn baby. Through antenatal care, many of the complication that arises during the course of pregnancy and childbirth can be minimized or prevented. At the same time many causes of death of women and newborn babies could be prevented through proper delivery and postpartum care. Nutritional status of mothers and children play a major role in deciding their health status.

Insuring proper nutrition of mothers and children is a vital requirement to maintain their good health and to protect them from different health problems, at the same time depriving mothers and children from proper nutritional requirement will expose them to major health problems that can endanger their health and well being.

Short birth interval has proven its adverse effect on both mothers and children, children born after short birth interval are more liable to be born with low birth weight and born prematurely.

At the same time children who are followed by pregnancy and childbirth during their first year will be deprived from the care they need because of pregnancy and arrival of the newborn baby, it will be more appropriate to

Prof. Mother and child health
Dept. Community Medicine\ Medical College\ Al-Nahrain University\Baghdad\ Iraq
have proper appropriate to have proper spacing of births for the sake of both mothers and children.

Iraq has suffered successive wars and civil disturbance away from peace, which all together have affected the health of mothers and children. Sanction imposed on Iraq following the occupation of the state of Kuwait has endangered the health and well being of all Iraqi population, but more have has incurred on mothers and children. This was shown with the progressive deterioration of the health and nutritional status of both mothers and children with steep acceleration of infant, under five maternal morbidity and mortality. Surveys showed that infant mortality risen by 2.8 times during the period Aug 1990 to Aug 1991 as stated by the national survey conducted by a team from Harvard University during Sept 1991. The educational status of mothers showed a positive relation with better health of mothers and children, mothers with higher educational level are more likely to look after their children in a better way, to secure their needs and demands and look after themselves and their families in a more rational manners. All the health needs of mothers and children could be met with simple and cost effective appropriate mechanics and tools. Through getting communication and proper exchange of experience many needs of mothers and children can be met instantly. Finally the status of women within community is very much related to health and environmental status, through provision for proper opportunity for women to upgrade their status, and to play their role in the developmental process. Emancipation of women is vital in this respect, through elimination of gender discrimination providing women the share they deserve with community.
Serum sFas in Non-Hodgkin's Lymphoma

Subh S. Al-Mudalal, Abbas H. Abdulsalam, Huda S. Baqer

Abstract

Background: Lymphomas are a heterogenous group of malignancies of B or T cells that usually originate in the lymph nodes. They are divided into Hodgkin and non-Hodgkin’s lymphomas. Disruption of the physiological balance between cell proliferation and death is a universal feature of all cancers. There has been an increasing interest in the role of apoptosis in tumorogenesis of lymphoma. On the molecular base apoptosis is caused by activation of the caspases through extrinsic and intrinsic pathways. Extrinsic pathway centers on tumor necrosis factor family, where the ligand will bind to the cell surface receptor and this in turn will induce apoptosis. Fas receptor is a member of the TNF/NGF receptor superfamily. Fas family is constituted of the receptor, ligand and soluble form. Soluble Fas will compete with Fas receptor for binding to ligand, thus interfering with Fas-L-mediated apoptosis.

Objective: To measure the level of serum sFas in non-Hodgkin lymphoma (NHL) and to determine the correlations of it with certain clinical and hematological parameters and chemotherapy treatment.

Patients and Methods: This study included 30 patients with NHL (19 males and 11 females), of them 14 patients were newly diagnosed along with 30 apparently healthy controls were involved in this study. The patients were interviewed with history taking, clinical examination and aspirating blood sample for estimation of serum sFas concentration using sandwich ELISA kit from Chemicon. Also serum CRP level, plasma LDH level, hemoglobin concentration, platelets count, WBC count and peripheral blood film were all performed using standard techniques.

Results: This study revealed that the serum sFas concentration was significantly higher in NHL patients than in healthy controls (p = 0.0001). This increase was significantly higher in pretreated patients and closely related to the pathological grade of NHL (p = 0.0002 and 0.0035 respectively).

Conclusions: Serum sFas is a simple, non-invasive and clinically useful laboratory parameter. It may be used as an auxiliary marker to assess the prognosis and the therapeutic planning in NHL.

Keywords: Fas, NHL.

Introduction:

Lymphomas are a heterogenous group of malignancies of B or T cells that usually originate in the lymph nodes, but may originate in any organ of the body, and share the single characteristic of arising as the result of a somatic mutation(s) in a lymphocyte progenitor [1].

Within the broad group of lymphomas, Hodgkin disease (HD) is segregated from all other forms, which constitute the non-Hodgkin lymphomas (NHLs) [2]. Disruption of the physiologic balance between cell proliferation and death is a universal feature of all cancers. The mechanisms and extent of this disruption in lymphoma cells determine the characteristics and evolution of the...
tumor, and this can be achieved through the deregulation of cell proliferation or inhibition of apoptosis [3].

Apoptosis, or programmed cell death, is a genetically regulated process in which the cell is active in producing its own death, a type of cellular suicide for the sake of maintaining homeostasis in the cellular community [4].

Apoptosis is caused by the activation of caspases. Caspases are a family of intracellular cysteine proteases that lie in a latent (zymogen) state in cells but become activated in response to a wide variety of cell death stimuli [5].

Though many pathways for activating caspases may exist, only two have been elucidated in detail; one of these centers on tumor necrosis factor (TNF) family receptors, where the ligand will bind to the cell surface and this will induce apoptosis (Extrinsic). The other involves the participation of mitochondria (Intrinsic), which release caspase-activating proteins into the cytosol, thereby triggering apoptosis [6, 7, 8].

Fas family is constituted of the receptor, ligand and soluble form. Fas (APO-1/CD95) receptor is a member of the TNF/NGF receptor superfamily. It is expressed on a variety of human B and T cell lines, on various normal human tissues and on many different tumor cells [9, 10].

Triggering of Fas receptor by its ligand (expressed in cells that show cytotoxic activity, including activated T-cells and natural killer cells) results in rapid induction of apoptosis by activating the cascade of proteases (caspases) [11, 12].

While the soluble form of Fas (sFas), which is devoid of the transmembrane region, will compete with membrane-associated Fas for binding to ligand, thus interfering with FasL-mediated apoptosis. Serum sFas level is increased in various diseases, including leukemia, lymphoma and SLE [5, 6, 7, 8, 13, 14, 15, 16].

In lymphoma the Fas superfamily can be used as tumor markers in the fields of tumorogenesis, clinical course, treatment and prognosis [7, 9, 10, 11, 12].

Aim of the Study:

To measure the level of serum soluble Fas in non-Hodgkin’s lymphoma patients. Furthermore, to determine the relation between serum sFas concentration and certain clinical parameters, hematological markers, stage, classification, prognostic parameters and chemotherapy treatment of non-Hodgkin’s lymphoma.

Patients, Control, Methods And aterial:

This study was conducted prospectively on 30 NHL patients, from October 2004 to June 2005, 19 were males and 11 were females, M:F ratio was 1.73:1.

The criteria for inclusion of the patients in this study were the followings:

1. No limitation of age or sex.
2. The patients were randomly selected.
3. The patients were diagnosed, clinically and histopathologically, by a consultant physician and an experienced histopathologist.
4. The patients were either newly diagnosed or already on treatment.

Twenty of these patients were attending the National Center for Hematology; while the rest were attending Al-Khadimiya Teaching Hospital and Baghdad Medical City.

A total of 30 apparently healthy control with an age range of 16-65 year were selectively included in this study. The criteria for inclusion of the control in this study were the followings [9]: They were selected in a way to be age (mean and range) and sex ratio matched for the patient group.
1. They had no fever within 1 week.
2. They are not receiving any medication.
3. They are not known to be pregnant.
4. They did not have a recent history of acute illness or any history of chronic illness.

A sample of venous blood was collected in plain and EDTA tubes.

Serum sFas present in the serum was measured by using sFas ELISA detection kit [from CHEMICON]. Serum CRP was estimated by using semiquantitative technique kit [from BIOKIT]. Plasma LDH was measured by using colorimetric method kit [from RANDOX]. Hemoglobin concentration, platelet count, WBC count, and peripheral blood film were all were performed using standard techniques\(^{[17]}\).

The patient is considered anemic if Hb < 13g/dl (PCV < 40\%) for males and if Hb < 11.5 g/dl (PCV < 36\%) for females\(^{[1]}\).

The patient is considered to have thrombocytopenia if Platelet count < 150x10\(^9\) and to have leucocytosis if WBCs count > 11.0x10\(^9\)\(^{[18]}\).

**Results:**

Thirty patients with malignant lymphoma, with an age range of 14-67 year and age mean of 46.2 year, were enrolled in this study. 14 of the NHL patients were newly diagnosed. The Descriptive statistics of NHL patients are listed in the following table 1:

Serum soluble Fas concentration and NHL patients:
The results reported in this study revealed that there was a highly significant difference (p = 0.0001) in serum sFas level between NHL patients mean ± S.E. (4961.9 ± 422 pg/ml) with range (1657 to 12430 pg/ml) and normal control mean ± S.E. (1993.8 ± 125.9 pg/ml) and range (988–2849 pg/ml) (Table 2).

There was no relation between serum sFas level and sex (p = 0.5338) or age (p = 0.67) of NHL patients.

The level of sFas in pretreated patients was significantly higher than in treated patients (p = 0.0002) (Fig. 1). Also the level of serum soluble Fas concentration was significantly decreased with the number of chemotherapy hours (p<0.0001)(Fig. 2).

Moreover, there was a highly significant difference between serum sFas level in NHL patients with high and intermediate grade versus those with Low grade lymphoma (p = 0.0035) and although the serum sFas level was higher in the in the high grade compared to the intermediate grade but it did not reach the level of significance (p=0.1786) (Figure 3).

Figure 1: Mean of concentration of serum sFas in pretreatment and on treatment NHL patients.
Figure 2: Relation between number of treatment courses and serum sFas level of NHL patients.
Discussion:

The present study is a prospective one aiming at evaluating the significance of the apoptotic inhibitor sFas using ELISA technique in patients with non-Hodgkin’s lymphoma. The study included the comparison of serum sFas to a number of clinicopathological variables of well-known significance.

The incidence of NHL was higher in males than in females and it was rising with age. These results are similar to those reported by Ministry of health cancer registry (15, 20) and Yasir (21).

However, serum sFas level of NHL patients did not depend on either age or sex, and these findings were in agreement with Niitsu et al (9).

This study demonstrated that the serum sFas level was significantly

Figure 3: The mean serum concentration of s-Fas in High, Intermediate and low-grade NHL patients.
higher in NHL patients than in healthy control (Table 2). Similar findings were reported by Sunil et al (7), Niitsu et al (9), Takeshi et al (11), Yufu et al (22), Munker et al (23) and Knipping (24).

The soluble Fas (which is a competitive inhibitor of apoptosis) compete with Fas receptor for binding to Fas ligand, thus interfering with Fas ligand-mediated apoptosis (25,26). Many studies had revealed that the defects in the Fas-mediated apoptotic pathway were associated with lymphoproliferative disorders and particularly lymphoma (27,28,29), therefore we may proposed that this increase in serum soluble Fas level is part of the disease process and may explain the tumorigenesis of NHL.

The serum sFas level was significantly higher in the more aggressive high and intermediate grade than in the low-grade lymphoma (Figure 3). Similar findings were reported by Sunil et al (7), Niitsu et al (9), Takeshi et al (11), Munker et al (23) and Knipping (29). Moreover John CR. and Ian TM. had proposed that the more the aggressive the lymphoma the more the antiapoptotic phenomenon (6,35), and this may explain the high level of sFas in the more aggressive grade.

This study had revealed that the level of serum soluble Fas concentration was significantly decreased with the number of chemotherapy courses (Figure 3) and it was significantly higher in pretreated patients compared to treated patients (Figure 2). This was in agreement with Takeshi et al (11) and Niitsu et al (9) who concluded that serum sFas concentration may be used as a valuable clinical tool and since it is well correlated to the clinical course and to the remission and relapse state therefore it may help in generating a more appropriate treatment plan. Similarly Niitsu et al (9) and Kondo et al (36) had found that NHL patients with a low pretreated serum sFas level had achieved complete remission while those with high serum sFas level were considered resistant to chemotherapy.

In this study there was no relation between B symptoms and serum sFas concentration. This finding was supported by Munker et al (23) and Knipping (24), who concluded that serum sFas level was not related to the clinical symptoms. Also no relation was found between the performance status and serum sFas concentration, which was in agreement with Sunil et al (7).

Moreover, LDH level which is a part of the IPI score that corresponds well with the tumor burden, extent of disease, response to treatment and relapse (22,33), was not related to the serum sFas concentration (p=0.1839). This finding was in agreement with Sunil et al (7), Takeshi et al (11), Munker et al (23) and Knipping (24).

Furthermore no relation was found between number of extranodal sites and serum sFas level (p=0.197) which was in agreement with Niitsu et al (9).

Also similar to Takeshi et al (11) study the serum sFas level was not affected by the clinical stage (Ann Arbor staging system).

Since this study had revealed that the serum sFas concentration was not related to the parameters that indicate growth and invasive potential of the tumor, including plasma LDH level, extranodal disease involvement and clinical stage of the tumor, therefore we might propose that sFas was not produced by the tumor cells. This finding is supported by Niitsu et al (9), Takeshi et al (11) and Munker et al (34). However the cells that produce serum soluble Fas are unclear yet. Takeshi et al (11) had proposed that it may be produced by T lymphocytes, which may reflect a responsive change, or immune activation in lymphoma and...
this may protect lymphoma cells from apoptosis \(^{11}\).

In agreement with Sunil et al \(^{7}\) and Niitsu et al \(^{9}\) this study had showed that the IPI score and age-adjusted IPI score were not correlated with the level of serum sFas (p=0.3102 and p=0.5130 respectively).

In this study 32\% of NHL patients had bone marrow involvement and this was in agreement with Julie et al \(^{35}\) and Raad \(^{36}\), however no relation was found between the bone marrow involvement and serum sFas concentration (p=0.337), which was supported by Sunil et al \(^{7}\) study.

Also there was no relation between hemoglobin concentration, platelet count or WBCs count and serum sFas concentration (p=0.945 ,p=2.456 and p=5.5457 respectively), these findings were in agreement with Takeshi et al \(^{11}\).

Serum CRP is another simple and valuable prognostic factor for NHL. Its increment is closely related to worsening of clinical course and increase LDH level \(^{37}\). In this study there was no relation between CRP and serum sFas concentration (p=0.1456) which was in agreement with Takeshi et al \(^{11}\), Munker et al \(^{23}\) and Knipping et al \(^{24}\).

**Conclusions:**

1. Since the antiapoptotic serum soluble Fas level was significantly higher in NHL patients, especially those who are pretreated and having the more aggressive disease. Therefore we may concluded that the serum sFas concentration has the prospect to become a clinically useful, simple, noninvasive, time-saving, prognostic and therapeutic planning auxiliary tumor marker test for the more aggressive non-Hodgkin's lymphomas.

2. Serum sFas maybe considered as a complementary independent test to the international prognostic index scores (IPI) for NHL.

THE VALUE OF NUCLEAR MORPHOMETRY IN BREAST CARCINOMA

Zainab Abdul Jabbar Hassan Al-Obaidi¹ FIBMS, Fawzia Fawzi² FIBMS, Hassanain Abdul Jabbar Hassan Al-Obaidi² MSc

Abstract
Background: Breast carcinoma is the most important malignant tumor in female population. There are many indications for the use of adjuvant chemotherapy in its treatment, which need a special selection of patients especially those with high risk & this is judged by several prognostic parameters such as patient’s age, tumor size, histological grade and others.

Nuclear morphometry has shown to be a good objective, quantitative method for the evaluation of prognosis, in which the Mean Nuclear Area & Standard Deviation of Nuclear Area showed an increase from the baseline value of normal breast epithelium to invasive carcinoma & found to be strongly correlated with the recurrence rate within 2.5 years.

Objective: To evaluate some prognostic parameters of breast carcinoma by the use of computerized nuclear morphometry.

Material & Methods:
Fifty-four cases of a histologically diagnosed invasive breast carcinoma of ductal type with a known tumor grade, size & patient’s age were reviewed. In each case an average of 5-10 microscopical fields were screened & 30 consecutive nuclei were determined at x400 magnification by the use of an image analysis system. Statistical analysis was performed using ANOVA, Tukey’s and t-test.

Results:
The mean values of nuclear area varied between the three histological grades (grade I, II and III) by using analysis of variance (p>0.01).

These values increased with increasing histological grade. (Tukey’s test: p>0.01).

Similarly the mean values of nuclear area were significantly higher in tumors measuring more than 5cm in diameter than those less than 5cm in diameter. (t-test: p>0.01).

On the other hand, the nuclear area in tumors of patients less than 50 years and more than 50 years of age showed no significant difference. (t-test: p<0.01)

Conclusions:
The Mean Nuclear Area was of value in the assessment of the histological grade, in which higher figures seen in higher grades. The same relationship found between tumors more than 5cm and those less than 5cm in diameter, in which higher values seen in tumors more than 5cm in diameter. On the contrary the importance of the Mean Nuclear Area was restricted when comparing tumors in patients less than 50 years and those more than 50 years of age.

In conclusion our data suggest that adapting a nuclear morphometric parameter e.g. nuclear area, which was performed on this study, may be a valuable objective tool in evaluating various prognostic indices.

Keywords: Breast carcinoma, nuclear morphometry, and prognosis.

IRAQI J MED SCI, 2007; VOL. 5(3): 13-17

Introduction:
Breast carcinoma is one of the most common malignancies in female population (¹).

There are several indications that early systemic adjuvant chemotherapy improves the treatment of patients with primary breast carcinoma. (², ³, ⁴) However the side effect of those drugs requires a selection of patient at higher risk for this type of therapy. (⁵)

Several prognostic parameters are included in this selection such as the patient’s age, size of the tumor, histological type, stage, histological & nuclear grade, mitotic index & axillary lymph node metastasis. (⁶,⁷,⁸) However

some of these parameters may have a subjective nature, like the mitotic index, histological and nuclear grade and according to certain studies the interobserver agreement rarely exceed 80-90%.\(^{(9,10)}\)

The advantage of quantitative methods is that they are objective and reproducible.\(^{(11,12)}\)

Nuclear morphometry has shown a prognostic significance in many studies,\(^{(13)}\) and that the mean nuclear area (MNA) & standard deviation of the nuclear area (SDNA) is an important prognostic predictor.\(^{(5)}\)

Investigators found a gradual increase in MNA from the baseline value of normal breast epithelium through benign diseases to invasive carcinoma\(^{(13)}\), and that patients with larger MNA & SDNA have worse prognosis.\(^{(5)}\)

Investigators also found that mitotic frequency & the variance of the nuclear area (NA) were most strongly correlated with recurrence rate within 2.5 years & since the quantitative microscopical studies of breast carcinoma has an objective nature, so NA measurement has a considerable advantage over the mitotic index study which is a value of subjective nature.\(^{(5)}\)

The MNA & variation of NA were also of prognostic significance in cytological specimens,\(^{(15,16)}\) and that the study of automated diagnosis & grading of breast carcinoma have been proved valuable.\(^{(17)}\)

Further, more a significant correlation found between morphometric features and estrogen receptor status.\(^{(18,19)}\)

In the present study we attempted to evaluate additional prognostic value of the nuclear profile to other prognostic variables.

**Materials and methods:**

Fifty-four cases of breast carcinoma were selected from the files of the histopathological laboratory at Al-Yarmouk Teaching Hospital in Baghdad, and reviewed later by two other pathologists; as invasive breast carcinoma of ductal type. All the examined samples were fixed in 10% formalin, embedded in paraffin; the sections were cut at 5µm & stained with hematoxylin and eosin. Histological grading was performed according to the modified Bloom-Richardson grading system on the basis of tubule formation, nuclear atypia & mitotic activity (grade I tumors have fairly normal appearance, grade III are poorly differentiated & grade II are intermediate between I and III.\(^{(20)}\)

Two other prognostic parameters were also investigated; namely the tumor size or diameter (more or less than 5cm) and patient's age whether (more or less than 50 years).

In each case, the most cellular areas were looked for at the periphery of the tumor. Necrotic and inflamed areas were avoided. An average of 5-10 high power microscopical fields was screened & 30 consecutive tumor cells with clear nuclear boarders were outlined. Overlapping nuclei were not measured. In each case these nuclei were examined at x400 (x40 objective magnification, x10 camera ocular), by the use of an image analysis system run by global lab image 2 software GLI2 (data translation Inc., USA). The system was composed of personal computer PC with frame grabber (DT3120k-1data translation Inc., USA) attached to the PC and a microscope (Olympus BH, Japan) with a video camera (KGB, cc-8603, Taiwan).

The images from the sections were obtained at 800X600 pixels resolution in BMP format. The digitalized images of the nuclear profile were outlined on the monitor screen using a computer mouse. The morphometric feature assessed was the nuclear area (NA).

The system was calibrated with a micrometer slide before each measurement. The data were transferred to a Microsoft® excel work sheet and were expressed in terms of micrometers.
and the differences in terms of morphometric measurement between the three groups studied were statistically tested using analysis of variance, and Tukey's (HSD) and t-test.

**Results:**

The mean values of nuclear area varied between the three histological grades (grade I, II, and III) by using analysis of variance (p>0.01). (Table -1)

These values increased significantly with increasing histological grade, (Tukey’s (HSD) test: p>0.01) (table -4). Similarly the mean values of nuclear area were significantly higher in tumors measuring more than 5cm in diameter than those less than 5cm in diameter (t-test: p>0.01). (Table-3)

On the other hand, the nuclear area in tumors of patients less than 50 years & those more than 50 years of age showed no significant difference. (t-test: p<0.01) (table-2)

Discussion:
Breast carcinoma is one of the most important causes of death in female population and in order to predict the tumor’s behavior many prognostic parameters have been introduced, some of which are subjectively judged, as the mitotic index, histological and nuclear grade with an interobserver agreement that rarely exceeds 80-90%.

From here the advantage of quantitative analytic methods has been introduced as an objective &reproducible tool for the evaluation of the tumor’s behavior.

In this work we attempted to study the value of nuclear morphometry in the evaluation of some of the conventional prognostic parameters, namely; tumor’s size, patient’s age and histological grade.

There was a significant difference in the value of the MNA between the three histological tumor grades (I, II and III) and between those tumors more than 5cm and those less than 5cm in diameter, while there was no significant difference of the MNA between tumors of (more than 50 years and less than 50 years of age).

This showed that the MNA was of value in the assessment of the histological grade, in those higher figures seen in higher grades. The same relationship found between the tumors more than 5cm and those less than 5cm, in which higher values seen in tumors more than 5cm in diameter. On the contrary the value of the MNA was restricted when comparing tumors in patients less than 50 years and those more than 50 years of age. One explanation for the latter finding might be explained by the improper age recording of the examined patients.

Similar results were obtained by other studies indicating the value of the MNA as an objective morphometric index. (13,21)

In conclusion our data suggest that adapting a nuclear morphometric parameter e.g nuclear area, which was performed on our samples, may be a valuable objective tool in evaluating various prognostic indices.

Causes of Partial Epilepsy in a cohort of Iraqi epileptic patients
Hasan Aziz Al-Hamani FICMS.

Abstract
Background: Partial (focal or localization related) epilepsy is the most common seizure disorder encountered in patients with epilepsy. These seizures are focal at onset that is emanating from localized region of the brain. Certain structural and metabolic abnormalities in the brain will predictably lower the epilepsy threshold. Seizure can result from either primary central nervous system dysfunction or underlying systemic diseases. The incidence of structural abnormalities was higher with increasing age of the onset of seizure and declined with long duration of history of epilepsy.

Objectives:
1) Identify the cause of partial seizure.
2) Clarify the association of these causes and the age of the patients.

Study: Prospective cohort study.
Setting: Al-Kademiyah Teaching Hospital.
Patients: 106 patients presented with partial seizure, the age of them ranged between 6-73 years, 52 males and 54 females.

Result: The abnormal neuroimaging occurred in (61%) of patients. Tumors occurred in about (19.7%) of patients most of them below 40 years of age while infarctions in about (25.5%) of patient above this age. (83.7%) of complex partial seizure patients had temporal lobe foci and (16.2%) in frontal lobe, while (49%) of simple partial seizure patient had frontal lobe foci, (22%) frontoparietal and (13%) had parietal lobe foci. (75.4%) of patient with simple partial seizure and (35.1%) with complex partial seizure had brain(structural) lesion.

Conclusion:
1. Infarction is a common cause of partial seizure in patients above the age of 40 and below this age was a tumor.
2. Partial seizure is associated mostly with organic brain lesions.
3. The incidence of structural lesion was decrease in patients with long history of partial epilepsy.

Key words: Seizure and Epilepsy

IRAQI J MED SCI, 2007; VOL.5(3):18-22

Introduction:
Epilepsy can be defined as an intermittent derangement of the nervous system due to “an excessive and disorderly discharge of cerebral neurones”. This was postulated in 1870 by Hughlings Jackson., and modern electrophysiology offers no evidence to the contrary (1).

Partial (focal or localization related) epilepsy is the most common seizure disorder encountered in patients with epilepsy. These seizures are focal at onset that is emanating from localized region of the brain (2).

Approximately 5-10 % of population will have at least one seizure during their lifetime, with highest incidence occurring in early childhood and late adulthood. (3)

If consciousness (The awareness of, and ability to respond to the environment) is preserved, the attack is termed, simple. If, however, the activity involves some parts of the brain dealing with awareness (such as the temporal or frontal lobes), then consciousness is affected and a complex partial seizure results. Further spread into the diencephalons and hence throughout the remainder of the cortex leads to a secondarily generalized seizure (4).

In the normally functioning cortex, synchronous discharge amongst neighboring groups of neuron is...
limited by recurrent and collateral inhibitory circuit. The inhibitory transmitter is GABA while the excitatory neurotransmitters are acetycholine, aminoacids glutamate and aspartate\(^4\).

In partial seizure there is paroxysmal depolarization of membrane of a local group of neurons, which corresponds temporally to the finding of a focal spike and wave complex on the EEG\(^5\).

Certain structural and metabolic abnormalities in the brain will predictably lower the epilepsy threshold\(^6\). Seizure can result from either primary central nervous system dysfunction or underlying systemic diseases. This distinction is critical. Since therapy must be directed at the underlying disorders as well as at seizure control\(^4\).

Seizures before the age of 20 years are rarely associated with tumors. If the patient is between 20-30 y of age the risk of progressive lesions goes up slightly\(^7\).

From 30 to 60 years, the incidence of primary brain tumor peaks, reaching approximately 15 percent in patients with PSSs. After the age of 60, the incidence of tumors starts to fall off again as a vascular cause becomes more likely\(^8\).

Approximately 30% of patients with PE have mass lesions like neoplasms or vascular malformations as the cause of their seizure disorders\(^9\).

The incidence of structural abnormalities was higher with increasing age of the onset of seizure and declined with long duration of history of epilepsy\(^10\).

The evaluation of the patients with a probable PS includes a variety of diagnostic and clinical evaluation in addition to the history and physical and neurological examination. These include EEG and neuro-imaging pictures. EEG most commonly used as a diagnostic test in assessment of patients with PE A yield between 60 and 93 percent has been claimed for this procedure when multiple recordings are used or when recordings are made after 24 hours period of sleep deprivation. Sphenoidal electrodes both the anterior and posterior ones improve the yield in patients with mesial temporal sclerosis whose routine EEG are normal. The CT and MRI are non-invasive studies that can determine the cause of seizure and assist in localizing the epileptogenic area. MRI has been demonstrated to be superior to CT in imaging epileptogenic lesion, like temporal sclerosis and cortical gliosis\(^12\).

The treatment of PE may be either medical or surgical, but medical treatment is the primary approach\(^13\).

**Patients and Methods:**
We take all patients referred for neurological consultation in Al-Kahdemyia Teaching Hospital, Baghdad Teaching Hospital & Al-Yarmok Teaching Hospital for the period from (November 2001-May 2003).

The patients with partial seizure and partial with secondary generalized epilepsy were enrolled in this study. This was secured through a detailed history, elaborate generalized examination and examination of the nervous system.

All patients had 16 channel EEG recordings (by use of Nihon Kohden Corporation: 4321F), some times more than one recording is needed with emphasis on activating procedure like hyperventilation, Each recording is for 20 minutes.

All patients had neuroimaginings like brain spiral CT (Somatotom Plus 4-Siemens ,Version C10B) with and without contrast when needed. MRI (Gyroscan NT 1.5 tesla power. Philips
Medical System) was done in patients with no abnormalities revealed by CT.

**Results:**

One hundred six patients were collected from those who visited neurological department of Al-Yarmok teaching hospital, Al-Kadhemia teaching hospital /Baghdad Teaching Hospital with symptoms and sign goes with partial epilepsy.

The age of the patients ranged between 6-73y. 52 males & 54 females.

In 65 (61%) patients the neuro-imaging study (MRI & CT) was abnormal, while 41(39%) patients no lesion can be defined.

The association between brain lesion and age of the patient was shown in table (1).

Sixty five patients with partial epilepsy had lesions that were revealed on MRI and CT. 21(32%) patients with tumors: 16 patients with glioma, 3 patient, with maningioma, 2 patients with cystic tumor, both of them had a strocytoma, Twenty-seven (42%) patients complained of infraction, 4 (6%) patients had intra-cerebral hemorrhage. Brain abscess is found in 5 (8%) patients. Encephalities occurred in 2 (3%) patients, while 6 patients (9%) had mesial temporal sclerosis.

In our study we found that there are 19 patients who had a history of febrile convulsions in childhood, 5 (26%) of them had focal area at fronto-parietal area while 14 (74%) patients had focal area of epilepsy at temporal lobe. In those patients focal area of epilepsy with temporal lobe had changes on brain MRI go with mesial temporal sclerosis in 6 (32%) patients. Neuro-imaging in patients with SPS revealed lesion in 52 (75.3%) patient from 69 patients, while there are lesions in 13 (35.1%) patients complained from complex partial epilepsy.

We found that when there are a long duration of epilepsy the abnormalities on neuro-imaging or structural brain abnormalities decrease

Discussion:

In our study there are 65 (61%) patients with partial epilepsy had abnormal neuro-imaging (CT and MRI), while there are no abnormalities in 41 (39%) patients. These results are slightly more than previously (23-55%) reported studies. This could be attributed to the fact that our study was hospital based and more stringent inclusion criteria of the patients in this study\(^{(14)}\).

Cerebral vascular accidents or diseases as a cause of partial epilepsy were found in 27 (25.5%) patients and mostly at age above 40 yr., which is more than previous studies \(^{(10,15)}\), which revealed that the percentage of vascular disease as a cause of partial seizure is 18%.

While the incidence of tumors a cause of partial epilepsy was found in about 21 (19.7%) patients and most of them are under the age of 40 years in comparison with 20% in previous reported studies and more than percentage reported in other studies (4-12\%) \(^{(7, 8, 16)}\). This can be explained by the nature of our study which is prospective with particular attention to find the cause of the partial epilepsy in our patients that were drained from the hospital with their presenting syndrome being partial epilepsy.

We found that the patients with simple partial seizures were 69 (65%) while 37 (35%) patients complained of complex partial seizures these results are comparable previous reported study \(^{(17)}\).

There is a high association of structural abnormality in the brain & SPS occurred in about 52 (75.3%), as compared to 13(35.1%) patients with CPS, our figures are comparable (48-71%) to previous reports \(^{(14,18)}\).

About febrile convulsion, we found there is increasing in its incidence with temporal epilepsy especially mesial
temporal sclerosis (32%) which was less than that of the previous reports (48%). This finding may be attributed to many patients misdiagnosed by the neuroimaging but there is no relation between a degree of sclerosis and atrophy in MRI and a history of seizure (19). These changes may occur in individual that never had seizure. In other study the identification of mesial sclerosis was incidental by MRI but significantly needs investigation (20).

We noticed that when there is a long history of epilepsy the incidence of structural abnormalities of brain lesions decreased while when there is short duration, neuro-imaging abnormalities will increased these result were corresponding to previous reported study (10,18).

**Conclusion:**
1. Infarction is a common cause of partial seizure in patients above the age of 40 and below this age was a tumor.
2. Partial seizure is associated mostly with organic brain lesions.
3. The incidence of structural lesion was decrease in patients with long history of partial epilepsy.

A STUDY ON THE BACTERIAL DISSEMINATION AND EXPERIMENTAL PATHOLOGY OF SALMONELLA PARATYPHI – AN INFECTION IN WHITE MICE

Khalil Hassan Znad Al-Joboury, PhD.

Abstract
Background: Paratyphoid infection remains an important public health problem with marked host specificity for humans or higher primates but not naturally virulent for mice except that using high inoculum of the paratyphoid bacilli.

Objective: 1. Study the bacterial dissemination through the organs of white mice. 2. Study the pathological changes associated with this experimental disease process

Methods: One LD$_{50}$ of the microorganism corresponded to $8 \times 10^7$ bacterial Cell/ml. However 10LD$_{50}$ doses were intraperitoneally used for mice to produce extensive disease process in mice. Following inoculation of mice the course bacterial dissemination and pathological lesions were studied at specific intervals and for 3 days post inoculation.

Result: The microorganisms were persistent in the spleen and liver for 21 and 17 days postinoculation respectively, where as the microorganisms persisted in the mediastinal lymph nodes and lungs for 9 days and kidney and heart blood for 5 days postinoculation. The main pathological lesions were initiated as a mild infiltration of neutrophils and edema in the spleen liver and lymph node the neutrophils infiltration will be gradually replaced by mononuclear cell infiltration and finally with fibroblasts proliferation.

Conclusion: The Salmonella paratyphi-A is of lower pathogenicity and virulence for white mice, through their dissemination in organs of white mice and associated pathological findings.

Keywords: Salmonella paratyphi-A infection white mice

IRAQI J MED SCI, 2007; VOL.5(3):23-30

Introduction:
Paratyphoid bacilli are enteropathogenic bacteria with marked host specificity, Salmonella paratyphi type A, B & C is strictly pathogenic for humans (or higher primates) but not naturally virulent for mice. To kill a mouse, it is necessary to give high inoculum intraperitoneally, death occurs within 1-4 days following the development of a toxic syndrome (1). In our country as in other parts of the developing countries, febrile illness due to typhoid and paratyphoid bacilli are common. Although the clinical picture, the epidemiological picture as well as diagnostic procedures of paratyphoid fever have been well studied, some aspects related to the role of bacteria in the disease process and the pathological changes associated with the disease still require some illumination. Thus, the objective of this study was to fulfill a required hypothesis that paratyphoid infection can be simulated in a suitable laboratory animal model that provides a picture for human paratyphoid, the present study aims at the followings: 1- Study the disease process, including the bacterial dissemination through the organs of the white mice.
experimentally infected with *Salmonella paratyphi*-A. 

2- Study the pathological changes associated with this experimental disease process in the white mice.

**Materials and methods:**

White mice, weighing 15-20 Gms, 2 months old, were obtained from Al-Kindi Company for Veterinary drugs and vaccines production. The mice were healthy and reared on concentrated food for two weeks before being used. A local strain of *Salmonella paratyphi*-A, isolated from the febrile patients, in the Ibn-Khatib hospital and their LD50 dose corresponded to $8 \times 10^7$ bacterial cell. A logarithmic phase growth of *Salmonella paratyphi*-A in trypticase soy broth at $37^\circ$C was taken, washed once in phosphate buffer saline, a suspension of a viable count of $10^9$ bacterial cell/ml was obtained. Fifty mice were intraperitoneally injected with 0.8 ml of *Salmonella paratyphi*-A suspension containing $8 \times 10^8$ bacterial cells (10 LD50). Two inoculated mice were sacrificed every two days including the dead mice for the period of one month. All the sacrificed and dead mice were studied for the purpose of:

1- Isolation of *Salmonella paratyphi*-A from the different organs of the experimentally infected mice, looking for bacterial dissemination in the organs.

2- For pathological study, small representative pieces from all the organs of infected mice were fixed in 10% neutral buffered formalin, processed routinely, cut at 5-µ thicknesses and stained with hematoxylin and eosin (H&E).

**Results:**

1- Distribution of *Salmonella paratyphi*-A in the organs of experimentally infected white mice:

During 30 days of experimental infection of mice with *Salmonella paratyphi*-A, an extensive dissemination of this microbe was found in the different organs at different intervals post infection (PI). It is evident (Table – 1) that the spleen and liver found to be the main target organs of invasion, whereas, kidneys and lungs were slightly invaded by this microbe. The spleen had the longest period of infectivity, which lasted for 21 days post infection, whereas, infectivity lasted for 17 days in the liver. Mediastinal lymph nodes and lungs harbored the organism for 9 days. The organisms were isolated from the kidneys and heart blood for 5 days post infection. The brain is free of bacterial isolation.

**Table –1:** Distribution of *Salmonella paratyphi*-A through the organs of white mice after intraperitoneal inoculation

The Pathological Findings:

Different pathological findings appeared in this experimental disease processes were as follows:

The spleen:
The earliest lesions were mild infiltration of neutrophils in white and red pulps of the splenic tissue (Fig. 1). These inflammatory cells were gradually replaced by mononuclear cells (lymphocytes and macrophages), and few fibroblasts through the second and third week post infection. Also there is extensive congestion and hyperplasia of white pulp and in the reticuloendothelial cells lining the red pulp. These lesions were completely disappeared through the fourth week post infection.

The liver:
It showed initially a mild aggregate of neutrophils in the sinusoidal and preisinusoidal areas of the hepatic tissue (Fig. 2), which is extensively congested and these inflammatory cell infiltrations were gradually replaced with few mononuclear cells (Lymphocytes and macrophages) (Fig. 3), through the second week post infection. These lesions were completely disappeared through the third week post infection.

Mediastinal Lymph Node:
There is extensive hyperplasia in the lymphoid follicles of the cortical region and in the reticuloendothelial cells lining the medullary sinuses (Fig. 4). Also there is extensive congestion of the lymphoid tissue.

The lungs:
It shows extensive congestion and mild interstitial pneumonic lesions (Fig. 5).

The Kidneys:
It showed only congestion and mild microthrombi in the renal tissue (Fig. 6).

The brain and other organs showed only congestion.
Fig. 1: Microscopic section of spleen tissue shows focal aggregate of neutrophils and edema in the white pulp (H&E) X 125.

Fig. 2: Microscopic section of liver tissue shows the presence of focal aggregate of neutrophils in the area adjacent to the sinusoids (H&E) X 250.
Fig. 3: Microscopic section of liver tissue shows infiltration of lymphocytes and macrophages replacing the neutrophils (H&E) X 500.

Fig. 4: Microscopic section of mediastinal lymph node shows extensive reactive hyperplasia (H&E). X 125
**Discussion:**

1- Distribution of *Salmonella paratyphi* - A in the organs of experimentally infected white mice:

Most studies on the typhoid and paratyphoid bacilli in mice have been limited by the fact that these organisms have low pathogenicity for this animal species. Thus microorganisms are strictly pathogenic for human being (or higher primates). To kill mice a high
inoculum of these microorganisms should be intraperitoneally given (1). These findings were confirmed by this work, a less extent disease process produced in mice when the inoculum introduced into the peritoneal cavity was \(8 \times 10^8\) bacterial cell of *Salmonella paratyphi* - A. Corresponding results were obtained by other workers, who showed that typhoid and paratyphoid like diseases were produced in mice using the paratyphoid bacilli type-B (2) and typhoid bacilli (3, 4 and 5). This study revealed that following the intraperitoneal injection of *Salmonella paratyphi* – A with the massive dose of \(8 \times 10^8\) bacterial cell, a less extent growth of this microorganism occurred in the spleen, liver, mediastinal lymph node, lungs and kidneys; the microorganisms reach in to the thoracic duct and to blood through 24 hours post infection. These results go along with those reported by Gerichter, Carter and Collins and AL-Joboury (6,7,5 and 2) for typhoid and paratyphoid bacilli.

**Pathological Findings:**

This study revealed mild lesions, initiated in the liver, spleen and mediastinal lymph nodes and consisted of mild infiltration of neutrophils, edema and congestion of blood vessels. These inflammatory cells infiltrations and edema were demonstrated by other workers (8 & 9) on murine Salmonellosis caused by *Salmonella typhimurium* and in mice infected with typhoid and paratyphoid bacilli (10, 2). Both workers demonstrated extensive neutrophil infiltration forming multifocal microabscesses in different organs, which is not observed in the present study and may be explained on the basis of virulence of the microbe used in the present study. During the second week post infection, the neutrophiles infiltration was gradually replaced by mononuclear cells (Lymphocytes and macrophages and plasma cells) infiltration without granulomatous type lesions which demonstrated by Naconeczna and Hsu (8, 9) on murine Salmonellosis caused by *Salmonella typhimurium* and AL-Joboury (10,2) on mice experimentally infected with typhoid and paratyphoid bacilli. The absence of granulomatous lesions in the spleen and liver in the present study may be explained on the basis of low virulence of the microorganism used in the present study, and therefore, during third and fourth week post infection, most of the infected organs will become free from any lesions. The healing of the lesions through these periods of post infection will indicate that the lesions were originally found at less extent, so easily healed. Other mild lesions such as, hyperplasia of lymphoid tissues, interstitial pneumonic lesions in the lung tissue and micro thrombi in the kidney were demonstrated in the...
present study. The occurrence of these lesions in these organs were explained as metastatic type lesions occurred by the microorganisms through, the hematogenous dissemination, such metastatic lesions were also reported in mice experimentally infected by typhoid and paratyphoid bacilli (2, 10) and in typhoid patients (11,12). No brain involvement by *Salmonella paratyphi* – A, is reported in the present study, these findings may be explained on the basis of low virulence of this microbe which did not reach into the brain through the metastasis.

**Conclusions:**

The results of this study on mice experimentally infected with *Salmonella paratyphi* – A differ from the results of the previous study obtained by AL-Joboury (2) on mice experimentally infected with *Salmonella paratyphi* – B in the followings:

1- The present study showed focal aggregate of neutrophils without microabscess formation and not accompanied by granulomatous lesion in spleen and liver, comparable to the focal microabscess and granuloma seen in the spleen and liver in the previous study on mice experimentally infected with *Salmonella paratyphi* – B.

2- No involvement of the brain tissue of the mice by the *Salmonella paratyphi* – A in the present study.

3- Mild nonspecific pathological lesions were seen in the lungs and kidneys of the mice in the present study.

4- The above findings indicate that the *Salmonella paratyphi* – A is of lower pathogenicity and virulence than of *Salmonella paratyphi* – B and for *Salmonella typhi*.

Carrier Detection of Duchenne Muscular Dystrophy by CPK Activity Testing and Conventional Needle EMG.

Abdul-Muttalib Abdul-Kareem Alsheikhly¹ FRCP, Salam Fouad Rabie² FIBMS, Hasan Azeez AL-Hamadani¹ FICMS.

Abstract

Background: Duchenne Muscular Dystrophy (DMD) is a dismal disease, which exhibits an X-linked mode of inheritance, characterized by progressive proximal muscular weakness, beginning in early childhood, wheel chair dependency by early teens and death from cardiopulmonary complications by the end of the second or third decade. Although the majority of carriers of DMD and Becker muscular dystrophy (BMD) are asymptomatic but they can be identified through minor clinical changes like limited weakness or occasionally bulky calves, and some may have elevated CPK levels and mild EMG changes, and as DMD is an incurable disease, and carrier detection and genetic counseling are an important aspect of the global approach to limiting the number of patients with DMD and BMD and of carriers.

The Objective of the study is to test the value of CPK and conventional needle EMG muscle testing in detecting carriers in a group of Iraqi females with their sons having DMD and BMD.

Patients and Methods: The study was conducted in AL-Kadhimiyah Teaching Hospital Section of Neurology from October 2002 to December 2003, where a group of 20 female carriers of DMD and BMD, from 15 families were studied and compared to other Control group of 20 females randomly picked up. To each female studied full medical history, neurological examination, including manual muscle power testing, and Pedigree analysis taken, and to each female in the study CPK testing, ECG, with cardiac Echo, and Conventional needle EMG were done.

Results: Only one female carrier (5%) had mild proximal muscle weakness, cardiac involvement only one (5%), had mildly dilated left ventricle but with normal systolic function. 11 (55%) female carriers had mildly elevated CPK above the upper reference range (170 U/L); 10 (58.8%) DMD, and 1 (33.33%) of BMD. And there is significant (p<0.05) difference in CPK activity between the two groups. There is negative correlation between the age of female carriers and the CPK activity. 9 female carriers (45%) total, (52.94%) of DMD had proximal myopathic EMG changes, which were more prominent in the upper limbs. And there is significant (P<0.05) difference in mean amplitudes of motor unit action potentials of Biceps Brachii, and Vastus Medialis muscles.

Conclusion: As the CPK and EMG testings are simple, non costly and readily available tests, and as they can be positive to some extent in a proportion of carriers so they can be performed on all possible carriers in the families of DMD & BMD as a simple screening test, especially the CPK, better to perform at an earlier age, and the EMG at an older age because it requires cooperation. This has a significant impact on genetic counseling, aiming at preventing the spread of this bleak disease.

Keywords: Duchenne, Becker, Muscular dystrophy, Female carriers, CPK and Conventional EMG.

IRAQI J MED SCI, 2007; VOL. 5(3): 31-38

Introduction:

Duchene muscular dystrophy (DMD) and Becker muscular dystrophy (BMD) are X-linked recessive traits. Thus males carrying the gene are affected, whilst heterozygous females are carriers but often unaffected. Carrier females will pass on the condition to 50% of their sons and 50% of their daughters that will be carriers, i.e. a 25% chance that a carrier will have an affected son.¹

Gowers was the first to deduce the genetic basis for the disease. In 1986 100 years after Gowers’ Kunkel identified the DMD gene and provided molecular
Carrier Detection of Duchenne Muscular Dystrophy ….. Abdul-Muttaleb et al.

genetic confirmation of the inheritance pattern (2).

The primary purpose of identifying carriers is to provide accurate information to women and their husbands about the risk that any of their children will inherit the disease (3). So carrier detection is an important aspect of the care and evaluation of patients with DMD and BMD and their family members (2). Before the discovery of Dystrophin gene in 1986, carriers can be identified from pedigree information, from physical examination, and from indirect laboratory tests, the simplest and most reliable being the Creatinin Phosphokinase (CPK) test (3).

Mild muscle weakness or enlarged calves are occasionally encountered in heterozygous females (3). Roses and colleagues have studied the female carriers and report a slight weakness and enlargement of the calves as well as elevated CPK values and abnormalities of the electromyogram (EMG) and muscle biopsy—all-slight in degree in over 80% of the patients (4). It has long been known that carriers of DMD may also have symptoms of the disease. Summaries of case reports until 1970 were reported by Penn and colleagues (5).

A separate group known as manifesting carriers is the result of incomplete Lionization of the maternal X-chromosome (1). The clinical picture of carriers with symptoms can vary from muscle pain and cramp on exertion at one end of the spectrum, to severe muscle weakness leading to wheelchair dependency on the other end (6, 7).

If weakness is present, it is commonly mild, predominantly asymmetric, and proximally distributed (6, 8, 9). The pelvic girdle is more frequently and earlier affected than the shoulder girdle. Age of onset is also variable, ranging from the first to the fourth decade. Onset before the age of 15 years usually leads to severe involvement (6, 10). A small minority of female carriers is symptomatic (2). Clinically apparent muscle weakness occurs in 2.5 to 20 percent of female carriers of a mutated Dystrophin gene (11). Carriers of BMD rarely have symptoms—since the first report by Moser in 1974 (3), only few instances have been described (8).

A major advance in clinical diagnosis was the discovery by Sibley and Lehninger (1949), amplified by Schapira et al. (1953), that serum activity of the enzyme, aldolase, was greatly increased in boys with progressive muscular dystrophy. After a number of other serum enzymes were found to be elevated, the CPK test introduced by Ebashi et al (1959) proved to be the most sensitive, and it was soon established that young boys with DMD invariably had extremely large elevations of serum CPK that were rarely found in autosomal recessive muscular dystrophy (3). Serum CK is also increased in approximately 70 and 50 percent of Duchenne and Becker carriers, respectively (12). The elevations are usually mild, up to three times the upper limit of normal, ranging from 2-10 times the upper limit of normal (11,13).

For many years CPK testing was the best method for carrier detection (2) as about two-third of definite carriers have abnormally increased serum CPK, but a normal CPK test is not conclusive evidence against the carrier state (3). There is some evidence that the detection rate for carriers is higher in childhood than in adults (3).

**EMG In Muscular Dystrophy:** Even though not diagnostic, narrows the differential diagnosis by effectively excluding primarily neurogenic processes such as spinal muscular atrophy. In general, the proximal muscles of the lower extremities may exhibit the more prominent EMG findings. The MUAPs in patients with DMD or BMD are typically of short
duration, particularly the simple (i.e., non polyphasic) MUAPs.

MUAPs amplitudes are variable (normal to reduced) and they are typically polyphasic from the variability in muscle fiber diameters, resulting in longer MUAPs durations. Quantitative EMG (using measurement of duration, amplitude, and number of phases of photographed muscle action potentials) has revealed abnormalities in 38 to 42% of definite and probable carriers. Occasionally, the EMG is abnormal in a woman with normal CPK activity (3).

Electrocardiography (ECG) In Muscular Dystrophy: Among patients with DMD extensive fibrosis of the posterobasal left ventricular wall may result in the characteristic ECG changes of tall right precordial R waves with an increased R/S ratio and deep Q waves in leads I, aVL, and V5-6. The disorder is also associated with conduction disturbances, especially intra atrial leading to a variety of atrial arrhythmias. Intra atrial conduction defects are more common than AV or infra nodal defects in DMD. Since 1967, abnormalities in ECG, like those seen in DMD patients, have been recognized in carriers of DMD (14, 15). It has become clear that severe cardiac involvement- dilated cardiomyopathy- can also occur in carriers, and may or may not be accompanied by muscle weakness (15, 16, 17).

Patients and methods:

The study was conducted in Al-Kadhimiya teaching hospital section of neurology from October 2002 to December 2003. Where we received families with cases of DMD and BMD, after assessment of their sons and reevaluation by senior neurologist, CPK testing, EMG and muscle biopsy, we managed to enroll 15 families with clear history and diagnosis of DMD or BMD, 13 families with DMD and 2 families with BMD. From these 15 families 20 mothers of affected sons with DMD or BMD were studied. We called them carrier's group. And for the purpose of comparison we randomly picked other group of 20 females with comparable ages who were mothers of normal sons and had no history of muscle diseases or systemic illness and no family history of muscular dystrophy. And all of them where instructed and informed about the aim of the study we called them control group. A signed consent was taken from all subjects in both groups for inclusion in the study.

Methods:

To each female in the 2 groups’ full medical history, neurological examination including muscles strength assessment by manual muscle testing using the medical research council scale, and calf circumference had been measured using special anthropometrics tape adapted from (BSN-JOBST, inc.) also the height and weight had been measured and family pedigree details taken from each mother.

And from each female in the 2 groups, 3ml of venous blood was taken for CPK testing (upper reference limit 170 U/L) and measured according to the RANDOX Enzymatic Colorimetric Method, also to each female ECG taken and in case of any abnormality transthorasic cardiac Echo was done, to each of the female studied a conventional needle electrode EMG, for the Deltoid, Bicepse Brachii, Triceps, and Abductor pollisis brevis (for the upper limbs, and Vastus Medialis, Rectus Femoris, Gastrocnemeus, and Tibialis Anterior muscles, (for the lower limbs) using Medtronic keypoint EMG machine.

Statistical Analysis:

We used the student t test to compare means of calf circumference, weight, height, ages, CPK and mean value of amplitude and duration between carrier and control groups and we used the correlation regression for the relation
between CPK activity and the age of the carriers.

**Results:**

**The Group of Carriers:** From the 15 families (13 DMD and 2 BMD), 20 female carriers (17 DMD and 3 of BMD), by family pedigree analysis we found that 12 females (60%) are obligate (definite) carriers and 8 (40%) are of sporadic cases. Their ages ranged (28-60 years), average 36.65, SD 7.52. No one had significant symptoms of muscle weakness, apart from one (5%) who had G 4+ proximal weakness in the pelvic girdle muscle. 4 carriers (20%) had calf hypertrophy (calf circumference >15 inches) and only 2 (10%) had rubbery or resilient calf muscle texture. Only one carrier (5%) had history of palpitation on moderate-severe exertion. And 3 carriers (15%) had ECG changes, 2 of them had R-wave in V1 and deep S-waves in V5-6. And only one had LVH and Echocardiographic changes of mildly dilated left ventricle, but with normal ejection fraction (normal systolic function). 11 female carrier (55%) had mildly elevated CPK activity above the upper reference limits of 170 U/L, 10 (58.82%) of DMD, and one (33.33%) of BMD. 9 carriers (45%), all of them carriers of DMD (52.94%), had proximal myopathic EMG changes of low mean duration and amplitudes of MUAPs and >15% polyphasias as shown in table (1).

**The Control Group:** 20 healthy mothers, their age’s ranges (20-46 years), average 31.5 SD 8.15 they were age, height and weight matched. No one had calf enlargement (calf circumference. >15 inches). Their mean calf circumference was 14.35 inches range (13.5-15), SD 0.46, compared to 15.05 inches ranges (13.5-17.5), SD 1.05 in the carrier group, but there is no significant difference in calf circumference between the two groups. Only two mothers from the control group (10%) had borderline CPK of 172, 175 U/L. And their mean CPK was 97.9 ranges (36-175 U/L), SD 42.7 Compared to 200.9 U/L as a mean, average (88-303 U/L), SD 74.76 in the carriers’ group. And there is significant change in CPK values between the two groups. Also we found a negative correlation between age of carriers and CPK activity. Only 10 females in the control group had done conventional EMG successfully with good cooperation while the others were reluctant to do the test and three of them were uncooperative during the procedure. While all mothers in the carrier group were cooperative during the procedure. The EMG findings were normal and devoid of abnormalities in the control group. While the carrier group 9 females (45%) had low mean duration, and amplitudes of the MUAPs with polyphasic potentials >15%. With no significant difference (p>0.05) was found between the carrier group and the control group. But we found a significant difference (p <0.05) in the amplitudes of Biceps Brachii, and Vastus Medialis muscles, between the two groups. As shown in table (2) 9 of the carriers (45%) of the total (52.94%) of DMD showed > 15% polyphasia, 5 carriers (25%) only in the proximal upper limb muscles, 3 (15%) had polyphasia in both upper and lower proximal muscles and only 1 (5%) had polyphasia only in the proximal lower limb muscles.

NS (not significant) p>0.05
S (significant) p<0.05

Discussion: In this study we tried to include as many carriers within each family as possible to increase the total number of definite carriers to keep ascertainment bias to a minimum. As four of the carriers came with their sisters who also had affected sons with DMD, and one carrier of BMD came with her daughter who also had an affected son. In our 20 female carriers 12 had definite X-linked pattern by pedigree analysis, and 8 mothers had only one or more affected sons (sporadic cases), in the past they were considered as probable carriers but new techniques to identify carrier status suggest that a
significant proportion of apparently sporadic cases are in fact the offspring of previously unrecognized carriers \(^1\). So from the 15 pedigrees 8 pedigrees with sporadic cases and 7 pedigrees with familial cases, as it has long been apparent that isolated cases of DMD are very common; Duchenne, himself, failed to recognize the familial nature of the disease in his original ten patients \(^3\). The question here is whether the female carriers of sporadic case is a true carrier of X-linked recessive or autosomal recessive dystrophy, and in our study all the families taken lacking female affections which excludes this possibility. In this study the cases of DMD were assessed by clinical examination, CPK testing, EMG and Muscle biopsy and we found that all the cases had early involvement around the age of 2-3 years with evident course of progressive muscle weakness and calf hypertrophy, elevated CPK and other query cases were excluded from the study. only one carrier had mild muscle weakness (5%).

the explanation of this low figure, might be due to the relatively small sample, and also we depend on the manual muscle power testing which has the drawback of being highly subjective. While in the Hoogerwaard, et al study they disclose more carriers with muscle weakness by the application of hand held dynamometry \(^11\).

As there is no significant difference in calf circumference between the group of carriers and the control group but still there is relatively high measurements >15 inches in 4 (20%) which still can be a relatively high figure while only two carriers (10%) had rubbery calf muscle texture and this can be explained due to the subcutaneous fat in females which can give a false impression of soft texture. No carrier had cardiac symptoms apart of one who had palpitation on severe exertion, and only three (15%) had ECG changes 2 had R-waves in V1 and relatively deep S in V5-V6 and one had evidence of LVH, but cardiac Echo were completely normal apart from mildly dilated left ventricle but with normal systolic function, this mild cardiac involvement might explained by skewed X-inactivation which is tissue specific.

CPK was in the past the best method for carrier detection, but the results can be difficult to interpret in ethnic and racial groups with normally elevated CPK levels e.g. blacks have a higher reference range than whites; CPK levels of blacks may exceed the laboratory-stated normal limits without the presence of any pathology \(^3,2\), so in our study we take a randomly selected sample of mothers who had normal children and have no history of muscular dystrophy nor of muscle weakness or any systemic illness, for purpose of comparison. As our female sample all are Iraqi, Arabic Muslims, and we only found that the CPK activity in the control group was borderline only in two females (172, 175 U/L) which might be regarded as trivial, but also refer to that it is a non specific test. And many factors affect the results and may give high readings, so we take into consideration these factors like strenuous exercise or muscle trauma, Even I.M injection or EMG needle (so the blood sample should be taken before the EMG examination) also any history of taking drugs that raise the CPK, should be sought in the history (like statins e.g.) Also haemolysed serum will give falsely elevated results.

In our study we found that the CPK activity was mildly elevated in 11 (55%) of the total carriers, and 10 (58.8%) of carriers of DMD. While it is elevated in only one (33.33%) carrier of BMD. And these findings correlate with the Hoogerwaard et al study \(^11\), also we found that the results of CPK, were statistically significant.

We found that there is a negative correlation between the age and CPK
activity of carriers, which support the opinion that the detection rate of CPK for carriers is higher in childhood than in adults (3) due to the possibility of selective loss of dystrophin-negative fibers with advancing age (13).

The quantitative MUAP analysis was carried out as described by Buchthal (18), in all subjects in the two groups, where we found there is a relatively low mean duration and amplitude, and >15% polyphasia, in the proximal muscles in 9 carriers (45%) in total, while it is (52.94%) in carriers of DMD, while it is normal in the control group and also in the carriers of BMD, which might be explained by the mild involvement in BMD. There is no significant difference in the mean durations and amplitudes between the two groups, but the mean amplitudes of Biceps Brachii, and Vastus Medialis muscles were found to be of significance.

Also we found that polyphasia >15% was found more frequently in the proximal upper limbs muscles (Deltoids, Biceps Brachii) it is found in 8 carriers (40%) , but present in 5 carriers (25%) in the Triceps ,but it was only found in 3 carriers in the Vastus muscle, which is against of what is known of the early and more involvement of the pelvic-girdle muscles in carriers of DMD, but it agrees with the Hoogerwaard et al (11) which showed more involvement of weakness of the shoulder girdle muscles. The EMG had the drawback of being relatively an invasive procedure, and requires patients cooperation, and was difficult in children, so our patients all are adults, and only 10 females from the control group had done the procedure with good cooperation and 7 refused the test and 3 were uncooperative so we consider only 10, while the carrier group all the mothers had good cooperation with the test, which might be that they felt commitment to their affected sons.

Conclusion: As the CPK and EMG testings are simple, non costly and readily available tests, and as they can be positive to some extent in a proportions of carriers so they can be performed on all possible carriers in the families of DMD & BMD as a simple screening test, especially the CPK, better to perform at an earlier age, and the EMG at an older age because it requires cooperation.

This has a significant impact on genetic counseling, aiming at preventing the spread of this bleak disease.

Association between serum Copper, Oxidized HDL and Glycemic control in patients with type 2 Diabetes Mellitus in relation to Microalbuminuria

Mohammed A. Latif Al Bayati ¹ MSC , Hashim M. Hashim ² MRCP , Ghassan A. Al-Shamma¹ PhD ,

Abstract

Background: diabetes mellitus (DM) is associated with a markedly increased mortality rate from cardiovascular and renal disease, not explainable by traditional risk factors. Although data are not yet conclusive, oxidative stress, dyslipidemia, glycemic control and possibly lipid peroxidation has been increasingly implicated in the pathogenesis of diabetic micro- and macrovascular disease. Little is known, however, about the role of copper in type 2 diabetes.

Aim: The present study includes measurement of free radical activity marker (lipid peroxides expressed as malondialdehyde (MDA) along with the serum and urine copper, serum lipid profile, glycated haemoglobin (HbA1c) in addition to urinary protein : creatinine ratio in 55 patients with type 2 DM (T2DM).

Results: The patients were divided according to the spot urine albumin excretion (urinary albumin ug / mg creatinine ratio) into two groups:- microalbuminurics & normoalbuminurics. The results were compared with those obtained from 37 age-matched apparently healthy control subjects. There was a significant elevation in serum malondialdehyde MDA, the percentage of oxidized non high-density lipoprotein (ox. non-HDL%) and serum copper with a significant reduction in the percentage of oxidized high-density lipoprotein (ox. HDL%) in the diabetic patients (particularity in the microalbuminurics) as compared with the control subjects. Serum MDA was significantly and positively correlated with serum copper in microalbuminurics and HbA1c% in both diabetic groups.

LDL size index was significantly increased in microalbuminuric T2DM patients as compared to the controls and normoalbuminurics indicating smaller LDL size in the diabetics in general and in microalbuminuric in particular.

Conclusion: the results of present study suggest an increase in free radical activity, dyslipidaemia and serum copper level favoring atherosclerotic state more in poor glycemic control in type 2 DM particularly in microalbuminurics. The suggested mechanisms underlying these events are discussed.

Key words: Copper, lipid peroxides, diabetes mellitus., Microalbuminuria.

IRAQI J MED SCI, 2007;VOL.5(3):39-46

Introduction:

Approximately 150 million people worldwide suffer from type 2 diabetes and it has been predicted that this number will double within the next 15 years (1), and its incidence is rising in developed and developing countries (2, 3).

The prevalence of type 2 DM is growing at an exponential rate (4). T2DM is characterized by insulin resistance coupled with an inability of the pancreas to sufficiently compensate by increasing insulin secretion, with onset generally in middle or old age.

Diabetic nephropathy is the most common cause of renal failure in the Western World (5).

Several risk factors have been related to the development of diabetic nephropathy (DN) in type 2 diabetic patients, such as hyperglycemia,
arterial hypertension, dyslipidemia, and smoking\(^6,7,8\). Microalbuminuria is a strong predictor of diabetic nephropathy and cardiovascular disease in both type 1 and type 2 diabetes mellitus\(^9\).

The present study will go further to relate oxidative stress events with microalbuminuria of type 2 DM.

**Material & methods:**

**A-Subjects:**

The study group comprised 55 patients (24 males and 31 females) with type 2 diabetes mellitus (mean age 51.6 +/- 8.1 years) diagnosed according to the WHO definition\(^10\). The patients were divided into two groups: microalbuminuric (group 1), n = 31 and normoalbuminuric (group 2), n = 24. All patients were recruited from the outpatient Diabetes clinic of the AL-kadhymia Teaching Hospital during the study period from 1 September 2004 to 30 March 2005. The main exclusion criteria included any recent illness, impaired thyroid or renal function, diagnosis of renal disease, treatment with estrogen or glucocorticoids, or other drugs except oral hypoglycemic and/or beta blocker antihypertensive drugs & pregnant women. All patients included in the study were nonsmokers; none was taking antioxidant supplements or drugs with known antioxidant activity. The mean duration of diabetes was (7.96 +/- 3.45 years).

The control group consisted of 37 healthy, sex- and age-matched subjects (48.92 +/- 8.9 years) They were all volunteers recruited from different places and from the staff of the medical college of AL-Nahrain University.

**B-Blood samples**

About 10 milliliters of venous blood were collected from each subject of the study after a 12- hour fast. Two milliliters of the blood were collected in EDTA containing tubes and sent to the hospital Laboratory for HbA1c assay. The rest was collected in plain plastic tubes; which was centrifuged at 3000 rpm for 7 min within about 30 minutes from the time of collection. The serum was used for subsequent measurement of creatinine, lipid profile (total cholesterol, HDLc, TG), total MDA Level, Oxidized HDLc and copper concentration.

**Urine samples:**

Random morning urine specimen was obtained from each subject in the study, to quantify albuminuria (albumin-to-creatinine ratio) & creatinine.

**Methods:**

Serum total MDA was measured by the thiobarbiturate method\(^11\) while serum lipids (Tc, HDL-c and TG) were measured by enzymatic methods using kits from bioMeriux, France. Serum LDL-c was calculated by Friedewald formula\(^12\). Serum oxidized HDL was measured by precipitation of all lipoproteins, except HDL-c, which was measured by phospho-tungstic acid – MgCl2 reagent. The supernatant was used for estimation of oxidized HDL by the same method used for the measurement of total MDA. Serum copper was measured by flame atomic absorption spectrophotometer after 1: 10 dilution with de-ionized water. Urine albumin was measured by staining with Ponceau S dye following the method of (Pesce and Strande 1973)\(^13\) and urine creatinine by alkaline picrate kinetic method\(^14\). Glycated haemoglobin was measured by Variant™ HbA1c program\(^15\).

Diabetic patients (n = 55) were divided according to urine albumin excretion measured in ug per mg creatinine (Table 1) into:-
1. patients with albumin-creatinine ratio of 30 - 299 µg/mg were considered microalbuminurics (n = 31)
2. patients with albumin excretion less than 30 µg albumin per mg creatinine were considered normoalbuminurics (n = 24)

Lipid peroxides presented as total MDA and oxidized HDL were measured, then the value of oxidized non-HDL was obtained by subtraction (Total MDA - oxidized HDL = oxidized non-HDL) as in table (2).

Serum MDA was significantly elevated in the microalbuminuric diabetic patients compared with the normoalbuminuric patients (P = 0.004) and control subjects (p <10^{-10}). MDA was also significantly higher in the normoalbuminuric patients than the control subjects (P = 6. 10^{-7}), as shown in table (2).

Serum total cholesterol (TC), triglyceride (TG), high density lipoprotein cholesterol (HDLc), low density lipoprotein cholesterol (LDLc), atherogenic index, AI, (expressed as LDLc / HDLc) and LDL size index (expressed as TG / HDLc) were measured in all groups studied, (table 3).

As expected from the results of serum LDLc and HDLc, both diabetic groups have increased (AI) as compared with the control subjects (table 4). Furthermore, microalbuminurics had significantly higher atherogenic index than the normoalbuminuric patients (P <0.05) both diabetic groups showed a significant increase in the LDL size index when compared with controls, Indicating smaller LDL in patient’s groups table (4).

Serum copper was higher in the diabetics than the controls being significantly higher in the microalbuminurics than the normoalbuminurics as shown in table (4).

There was a significant positive correlation between serum copper and each of total MDA level and the urine albumin / creatinine in the microalbuminurics only. (Fig 1 & 2)

**Discussion:**
Most published studies have found increased Lipid Peroxides in T2DM patients (16, 17)

Serum MDA was significantly higher in the microalbuminuric than normoalbuminuric patients. These results confirm earlier reports (18, 19). A positive correlation between albumin excretion and plasma Thiobarbiturate reactive substance levels was also found (20)

However, not all instances of diabetes result in elevated oxidation. For example, a lower TBA reactivity in tissues of rats with alloxan - induced diabetes (21) and similar levels of MDA in micro-or normoalbuminuric type 1 DM patients were found by others (22, 23). The suggested biochemical mechanisms for increased lipid peroxide in DM patients are (24):

- Increased non-esterified fatty acids from increased lipolysis result in an increase in MDA.
- Peroxidative damage of membrane lipids.
- Lipids are more readily oxidized in the presence of increased glucose concentrations.
- Reactive oxygen species (ROS) can also be generated within the kidney by macrophages and polymorphonuclear leucocytes. In inflammatory cells, different sources of ROS have been suggested.
- Transition metals (copper and iron) catalytically activate the oxidation of polyunsaturated fatty acids. An enhancement in plasma transition metal concentration has been noted in diabetic animal models and in...
diabetic patients showing complications (25).

The higher atherogenic index (AI) and the presence of smaller LDL particle size in the diabetics were reported to associate the increase in their oxidation susceptibility which is consistent with the present results and agree with previous reports (26-28). This is further aggravated by the poor glycemic control indicated by the higher HbA1C level.

In another study poor glycemic control correlated significantly with micro- and macroalbuminuria in type 2 DM patients (29). It may be concluded that poor glycemic control may be considered as a risk factor for the progression from normo- to microprotienuria in type 2 DM (30).

The higher serum copper in diabetics, particularly in the microalbuminurics, is thought to be another event of oxidative stress (fig.1).

Serum Cu level was reported to be affected by renal excretion and kidney disease which is one of the major complications of diabetes (31). In the present study Serum copper correlated positively and significantly with urinary protein excretion in microalbuminurics (fig. 2).

Hypothetically glycated proteins bind transition metals such as copper and iron, and that such 'glycochelates' accumulate within the vasculature in diabetes and catalytically inactivate endothelial derived relaxation factor (EDRF) (32).

In the presence of available cellular reductants, copper in low molecular weight forms may play a catalytic role in the initiation of free radical reactions. The resulting oxyradicals have the potential to damage cellular lipids, nucleic acids, proteins and carbohydrates, resulting in wide-ranging impairment in cellular function and integrity (33).

HLA-Class II Risk Alleles Control T-Lymphocyte Proliferation in Response to Enterovirus and Adenovirus Antigens and IgG Antibody Prevalence in Newly Diagnosed T1DM Children

Eman M. Saleh1 Ph.D, Nidhal abdul Mohymen2 Ph.D.

Abstract
Background: Viral infections are implicated in the pathogenesis of type 1 diabetes mellitus (T1DM) in a number of studies, and playing a role in the initiation of beta-cell damaging process.

Objective: To evaluate the T-cell proliferation in response to enterovirus antigens including coxsackievirus B and poliovirus in addition to adenovirus in an HLA-matched population of children with T1DM and children who were healthy, in addition to screening for specific anti-viral IgG antibodies.

Subjects and methods: A total of 60 Iraqi T1DM children were included in the presents study. They were newly diagnosed diabetics. For the purpose of comparisons, 50 apparently healthy children were selected. HLA typing was measured by microlymphocytotoxicity, while MTT assay was used for lymphocyte proliferation by culturing peripheral blood lymphocytes (PBLs) with Con-A, Coxsackievirus B3 (CVB5), Adenovirus 3, 4, and 7 serotypes, and Poliovaccine. Serum IgG against these viruses were detected quantitatively with an indirect ELISA.

Results & conclusion: No significant differences were shown in the PBL proliferative percentage in response to Con-A mitogen and tested viruses (CVB5 and adenovirus) between T1DM and healthy controls, but PBL proliferative percentage of patients showed a significant decline in response to poliovaccine. Strong T-cell proliferation in response to the tested viral antigens were observed and was related to HLA-DR4 and HLA-DQ3 antigens, whereas the HLA-DR3 and HLA-DQ2 alleles were associated with week responsiveness to the same antigens. High significant mean proliferative percentage for all tested viruses were detected in those patients who were sero-positive IgG as compared to the sero-negative IgG diabetic children.

Conclusion: In children with new-onset diabetes, responses were generally decreased, but higher in children who carried risk HLA-class II alleles and who were sero positive to anti-viral IgG antibodies.

Key Words: T1DM, HLA class II alleles, Lymphocyte proliferation, Anti-CVB5 IgG, Anti-polio IgG, Anti-adeno IgG.

IRAQI J MED SCI, 2007; VOL.5(3):47-56

Introduction:
Epidemiological studies indicate that autoimmune diseases such as type 1 diabetes mellitus (T1DM) have a strong environmental component to their pathogenesis (1,2). There is a considerable body of evidence suggesting that involvement of several groups of viruses, but particularly those of the enterovirus genus, in the development and / or acceleration of T1DM (3). Coxsackie virus B4 (CVB4) - specific IgM responses are more common in newly diagnosed subjects with T1DM than in healthy control subjects (4). The finding of viral RNA in circulation at the onset of the disease have further support the role of enteroviruses (5).
Viral infection like other environmental risk factors can probably induce β-cell damaging processes only in individuals with genetic T1DM susceptibility. The most important risk genes are located within the HLA gene complex, where HLA-DQ alleles associated with increased susceptibility to or protection against T1DM can be defined (6). Enterovirus (EV) infections possibly occur predominantly in individuals with the DQA1*0501, DQB1*02 haplotype, who usually are also positive for HLA-B8 and HLA-DR3 alleles (7, 8). HLA may also influence immune responses to EV antigens in comparison occurs between patients and control individuals (9).

Few studies have focused on T-cell / virus interaction. In the present study T-cell proliferation in response to enterovirus antigens including coxsackie virus B and poliovirus in addition to adenovirus was analyzed in an HLA-matched population of children with T1DM and children who were healthy, and whether HLA alleles modified the cellular immune responses to the viral antigens.

**Subjects, Materials and Methods**

**Subjects:**

Sixty Iraqi T1DM children were subjected to this study. The patients were attending the National Diabetes Center at Al-Mustansiriya University during the period May 2004 - October 2005. Their ages ranged from 3 - 17 years, and they were new onset of the disease (diagnosis was from one week up to five months). For the diagnosis of Diabetes Mellitus, the criteria as listed in the Expert Committee of Diagnosis and Classification of Diabetes Mellitus, 2003 was used. All the patients were treated with daily replacement doses of insulin at the time of blood sampling. Fifty healthy children were selected, who have no history or clinical evidence of type 1diabetes or any chronic diseases and obvious abnormalities as a control group. These children were compared with T1DM children and matched for sex, age (4-17), and HLA-DR and DQ risk alleles as represented in table -1 and 2. The patient and control subjects were divided into two groups according to their ages, equal or less than 10 years and more than 10 years old.

**Collection of Blood Samples:**

Ten milliliters of venous blood were collected from each subject. Eight milliliters of blood were put in heparinised test tube (10 U/ml) and used for lymphocyte separation for the detection of HLA polymorphism and lymphocyte proliferation. Heparinised blood was processed as soon as possible. The remaining blood was drawn into plain test tube and the serum was separated by centrifugation at 2500 rpm for 10 min., divided into aliquot and kept at-20°C until used.

**HLA Typing:** It was carried out by microlymphocytotoxicity assay as described by (11).

Lymphocyte proliferation using MTT assay:
Peripheral blood lymphocytes (PBLs) were isolated using Ficoll-isopaque gradient centrifugation (Flow-Laboratories, UK). The washed PBLs were resuspended in complete RPMI-1640 medium (Euroclone, UK) supplemented with 10% heat inactivated AB serum (National blood transfusion center); Hepes; crystalline penicillin (1,000,000 IU) and streptomycin (1gm)(Pharma-intersprl, Belgica), and the final lymphocyte concentration was adjusted to 1-2x10^6 cells / ml.

Triplicate incubations of 100 μl of cell suspension with antigen(s) in 96 flat-bottom microculture plates for 3 days at 37°C in a humidified 5% CO₂ incubator. Then 20 μl of 1-[4,5-dimethylthiazol-2-yl]-2.5-diphenyl tetrazolium bromide (MTT) (Sigma, Germany) working solution was added to each culture well and the culture were incubated for further 4 hrs. The converted dye was solubilized by adding acidic isopropanol. The absorbancy was read using microculture plate reader using a wave length of 570 nm (12).

The antigens were:
CVB5 antigen solution (1:5 dilution) (KBR-CF antigen Vero, France),
poliovirus Trivalent Vaccine (1:5 dilution) (Polioral Trivalent; Chiron), and adenovirus type 3,4,7 solution (1:10 dilution) (KBR-CF antigen type 3, 4, 7, Vero). The final concentration or dilution for the three viral antigens was achieved according to the result of MTT serial dilution run of these antigens.

Con-A mitogen (100 μg/ml) was used as a mitogen positive control.

The percent of proliferative response of lymphocytes was calculated by the following formula:

\[
\% \text{ Proliferation} = \left( \frac{\text{Absorbancy of experimental wells}}{\text{Absorbancy of control wells}} - 1 \right) \times 100
\]

**Virus antibodies:**
IgG class antibody was measured against purified CVB5; adenovirus antigen (serotype 4, 5, 7) and poliovaccine using indirect ELISA method as described by (13, 14). Sample value lie below the cutoff value (mean negative + 2 SD) were considered negative. Those who were equal or greater than cutoff value were considered positive (15).

**Statistical analysis**
Regarding of HLA and disease association the frequency distribution for selected variables was done. Student t-test was used to measure the differences between two means; the results were expressed as means ± standard error (SE). The single Factor ANOVA (F-test) was used in this study to find out whether the difference between more than two groups of samples is significant or not. Pearson Correlation (R), which measures to what degree the two variable observations are correlated to each other was employed in addition to Chi Square test.

**Results**
**Lymphocyte Proliferation:** This test was performed to study whether the different viral antigens have any association with the proposed cell mediated immune (CMI) activation or not after incubation.
with peripheral blood lymphocytes (PBLs) of T1DM patients and healthy controls. The results of mean proliferative percentage in response to Con-A were represented in table (3). A similar mean lymphocyte proliferation percentage in response to Con-A mitogen was absorbed among patients and control groups, but newly diagnosed T1DM patients tended to have a lower non significant proliferative percentage than control subjects ≤10 years old (83.33 vs. 85.93%, \( P_1=0.82 \) ) and in >10 years old group (86.04 vs. 92.7% , \( P_1=0.62 \) ).

**Role of Viral Antigens in Functional Activation of PBL:**

Considering the response to different viral antigen, a lower mean proliferative percentage was seen among patients ≤10 years old in response to CVB5 compared to controls (36.67 vs 49.16%) and among patients >10 years old than controls (38.87 vs 51.20%). Those differences failed to reach significant levels in both age groups (\( P_1=0.061, \) and 0.14 respectively) (Table - 4).

Significant decline of proliferative response against poliovaccine was seen in T1DM patients (34.44%) compared to controls (47.38%) (\( P_1=0.045 \)) in ≤10 years old group and >10 years old group (28.30 vs. 40.86%, \( P_1=0.004 \) ) (Table - 4).

A non significant (\( P_1=0.82 \)) proliferative percentage decline in response to adenovirus was observed in ≤10 years old patients (19.97%) compared to controls (20.67%) and also in patients >10 years old (23.02%) in comparison with controls (28.61%) (\( P_1=0.23 \)).

No statistical differences appeared in the mean lymphocyte proliferative percentage between patients in both age groups against CVB5 (\( P_2=0.57 \)), poliovaccine (\( P_2=0.14 \)) and Adenovirus (\( P_2=0.57 \)).

**Relation of HLA Class II Alleles with the PBL Proliferation Percentage in T1DM Patients:**

At HLA-class II region, highly significant increased frequencies of DR3 (53.33 vs. 26.25%) and of DR4 (50.0 vs. 12.5%) were observed in the patients compared to controls (\( P=9.7 \times 10^{-3} \) and \( 1 \times 10^{-5} \) respectively) (data was not shown). At HLA-DQ loci, two antigens DQ2 and DQ3 were significantly increased in the patients compared with controls (DQ2: 33.33 vs. 15.0%, \( P=0.009 \); DQ3: 40.0 vs. 20.0%, \( P=0.008 \)).

To find out any relation between the HLA-class II risky alleles (genetic factors) and proliferative percentage of MTT (CMI level), ANOVA test was applied to compare the proliferative percentage in patients with HLA-DR risky alleles (DR3; DR4 and DR3/DR4) with those patients who had other alleles. The results represented in table -5 showed that the mean PBL proliferative percentage in response to different tested viral antigens was significantly higher in the patients with DR4, DR3 and DR3/DR4 serotypes compared with the children carrying other alleles. The significant levels scored \( P=0.021 \) in response to CVB5, \( P=0.031 \) in response to poliovaccine, and \( P=0.041 \) in response to adenovirus. Moreover, the mean proliferative percentage was significantly higher in patients carrying DR4 allele than those patients with DR3 alleles in response to CVB5 (62.67 vs. 43.32%, \( P=0.038 \)), to poliovaccine (59.86 vs 38.40%, \( P=0.031 \)) and to adenovirus (46.02 vs. 22.48%, \( P=0.046 \)).

Concerning the HLA-DQ risky alleles (DQ2, DQ3, DQ2/DQ3), our results presented in table -6 showed a significant increase of proliferative percentage in patients carrying different HLA-DQ risky alleles compared with the patients who lack these alleles. The
results scored as significant levels of \( P = 0.032 \) in response to CVB\(_5\), \( P = 0.038 \) in response to poliovaccine, and \( P = 0.042 \) in response to adenovirus (\( P = 0.042 \)).

As detected in table -6, the proliferative percentages were significantly higher in patients with DQ3 alleles than in patients with DQ2 alleles in response to all tested viral antigens.

**Anti-Viral IgG in T1DM Patients**

Seropositivity against the 3 viral antigens was significantly higher in diabetics than controls. Only 12 patients out of 60 were sero-positive (20%) compared to 4 healthy individuals out of 50 (8%) who were sero-positive for anti-CVB\(_5\) IgG. These differences were statistically significant (\( P=0.048 \)).

Nineteen patients (31.67%) were sero-positive for anti-polio-IgG compared to 13 (26%) healthy controls, and no difference appeared between both groups (\( P = 0.649 \)), whereas only 4 patients were sero positive for anti-adeno IgG (6.67%) compared with the control group who were all sero-negative. This difference was not significant between the two groups.

**Relation between Mean Lymphocyte Proliferation Percentage and Anti-Viral IgG in T1DM Patients**

To detect any relation that can clarify if the PBLs were primed previously by the same viral antigen. The results represented in table -7 showed a significant increase of mean proliferative percentage in response to CVB\(_5\) in the patients who were sero-positive for anti-CVB\(_5\)-IgG compared with the sero-negative patients (50.58 vs 22.99%) (\( P=0.048 \)).

The mean proliferative percentage for sero-positive and sero negative anti-polio-IgG patients is illustrated in table -8. It was found that the patients who were sero-positive for anti-polio IgG had higher proliferative percentage reading in response to polio-vaccine (31.48%) than those patients who were sero-negative (20.61%) and these differences were significant (\( P=0.039 \)).

The study also demonstrated increased mean proliferative percentage of PBLs in response to adenovirus in sero-positive anti-adeno IgG patients in comparison to sero-negative anti-adeno IgG patients (30.10 vs. 14.16%) and again these differences reach the significant level (\( P=0.042 \)) (Table -9).

Moreover, the present findings also revealed a significant positive correlation between the PBL proliferative percentage in response to CVB\(_5\) and anti-CVB\(_5\)-IgG (\( r =0.412 \)). Strong negative correlation was also detected between proliferative percentage in response to adenovirus and anti-adeno-IgG (\( r =-0.635 \)) while the correlation found with the anti-polio-IgG was weakly positive (\( r = 0.101 \)).

Discussion:

Functional Activity of PBL:

The use of lymphocyte proliferation technique is based on the capability of the lymphocytes for responding to an antigen (specific response), which has induced memory lymphocyte, either by vaccination or by natural infection. These lymphocytes, when they are repeatedly contacted with antigens, have a blastogenic transformation \(^{(16)}\).

The proliferative percentage of PBLs has been found lower in T1DM patients than in healthy controls in response to Con-A. Considering the responses to viral antigens, proliferative responses against CVB<sub>5</sub> and adenovirus were tended to have a lower percentage in T1DM patients than controls, but these values were not statistically different, while the proliferative responses against poliovaccine were significantly lower in patients especially in >10 years old group than controls. The low proliferative responses against CVB<sub>5</sub> antigen at disease onset is in agreement with other studies showing reduced T-cell proliferation against CVB<sub>5</sub> \(^{(17)}\), while the same investigators found in previous
study, no differences in T-cell proliferation against CVB₄-infected lysate between diabetic patients and healthy-non diabetic individuals (18). Another report conducted by Juhela et al., 2000 found that PBLs of the children at onset of T1DM had significant weaker responses to purified CVB₄ and non-significant decrease in response to poliovirus type 1 and 3 than healthy children, while the responses to adenovirus did not differ between patients and controls. Temporary decline in T-cell responsiveness at diabetes onset has also described in GAD peptide that contains the homology region to the CVB₄ 2C protein (20).

The results of these studies and the present study are subjected to several interpretations. One explanation is that, decreased responses of PBLs are due to redistribution of virus-specific T-cells, with virus-responder cells presumed to have homed to the pancreas and therefore unavailable for detection in peripheral blood (21), and so T-cell responses to various viral antigens may be suppressed at the onset of the disease. On the other hand, Varela-Calvino et al., 2002 indicated abundance of circulating primed CVB₄ specific responder T-cells that secretes IFN-γ in T1DM patients with relative lack of proliferation. These finding have been related to two broadly defined phenotypes of memory T-cells characterized by (22). Primed (memory) T-cells with the capacity to proliferate termed as "central memory" TCM cells, and lack immediate effector function and predominantly produce IL-2, the major T-cell growth factor to support proliferation and express CCR₇, a chemokine receptor, that direct homing to lymph nodes. In contrast the primed memory cell subsets that produce the proinflammatory cytokines IFN-γ during an immune response termed "effector memory" subset TEM, those cells do not express CCR₇, present in the circulation at sites of infection or tissue inflammation and release cytokines.

**Relation of Lymphocyte Proliferation with HLA:**

The present results indicated that stronger T-cell proliferation in response to CVB₅, poliovaccine and adenovirus were related to HLA-DR4 allele and HLA-DQ3 allele; whereas the HLA-DR3 and HLA-DQ2 were associated with weak responsiveness to the same antigens. These results are in agreement with a report by Bruserud et al., 1985 who found that DR4, which is in linkage disequilibrium with the HLA-DQB1*0302 allele, is associated with strong T-cell responses; whereas HLA-DR3 associated with HLA-DQB1*02 allele associates with weak T-cell responses to enterovirus antigens. Another study conducted by Juhela et al., 2000 demonstrated the same observation in T-cell responses to enterovirus antigens in T1DM patients.

**Anti-Viral IgG**

The present results described finding of IgG antibodies against CVB₅ to be more frequent (20%) in T1DM patients than in controls (8%). A low prevalence of specific CVB-IgG may be due to the use of only one CVB serotype (CVB₅) and there may be another CVB serotype in the sera of T1DM patients, which is not detected. The frequency of IgG antibodies against poliovirus (Oral Sabin) was more (31.67%) in diabetic patients than in controls (26%). Also IgG antibodies against adenovirus were detected in only four diabetic children (6.67%).

The presences of CVB₅, poliovirus and adenovirus specific IgG antibodies
are evidence of previous infection in T1DM children. This fact was confirmed by measuring the PBLs proliferative percentage in sero-positive IgG diabetic children in vitro in response to CVB5, poliovirus and adenovirus, and the results indicated a high significant mean proliferative percentage for all tested viruses in those patients as compared to the sero-negative IgG diabetic children. This means that PBLs of sero-positive IgG patients were boosted earlier either by natural infection or vaccination.

The low prevalence of anti-polio-IgG determined in healthy children may indicate a failure of poliovaccine to enhance the immune system, although these children presumably had taken many boosted doses of oral poliovaccine. Several studies have found CVB-specific IgM antibodies to be more common in newly diagnosed children compared to healthy individuals (19,23). Others detected an increase of anti-enterovirus antibody levels (both IgM and IgG) preceding the appearance of signs of autoimmunity reflected either by synthesis of several autoantibodies or the development of clinical disease (24). In contrast Tuvemo et al., 1989 and Emekdas et al., 1992 found no evidence of increased antibody frequencies against CVB1-6 serotypes at the onset of childhood diabetes. A lower antibody titer against CVB3-5 serotypes and adenovirus-7 were also demonstrated in newly diagnosed TIDM children than in healthy controls (27).

Enteroviruses could be involved in the pathogenesis of T1DM. During infection, viruses may reach the pancreatic islet and destroy insulin-producing β-cells by virus-induced cytolysis (28). Alternatively, β-cell damage might result from virus-induced inflammatory reactions through producing inflammatory cytokines (IL-1β, IFN-α… etc.) (29), in addition β-cell destruction might be based on molecular mimicry, because immunological cross-reactions between enteroviruses and β-cell autoantigens (GAD-65, Tyrosin phosphatease IA/IA3 can take place at least in vitro (14).

In conclusion, the present results show that T-cell proliferation in new onset Type 1 Diabetic children were decreased, but higher in children who carried risk HLA-class II alleles and who were sero positive to anti-viral IgG antibodies.

Oxidized lipoproteins in hypertensive patients on different modalities of treatment.

Faisal Gh. Al-Rubaey MSc, Abdul Rahman A. Al-Bazzaz PhD, Ghassan A. Al-Shamma PhD.

Abstract
Background: In addition to hypercholesterolaemia and smoking, hypertension, a chronic disease with many cardiovascular complications, is one of the major risk factors for cardiac ischemia, and the main risk factor for cerebrovascular disease. Recent studies have demonstrated some unwanted effects on lipid profile and trace element metabolism caused by antihypertensive drugs.

Aim: To elucidate the role of oxidative stress and lipid peroxidation in hypertension and the effect of different medical therapies on these parameters.

Subjects and methods: The present study included measurement of serum lipid profile, total lipid peroxidation, oxidized HDL (Ox-HDL), and urinary protein in 69 patients aged 30-70 years. They were three groups according to the type of therapy: (atenolol, captopril & no pharmacological antihypertensives, NPAHT).

The results were compared with those of 45 apparently healthy controls (age range = 30-66 years).

Results: showed a significant elevation in serum malondialdehyde (MDA) and the percentage of oxidized non high-density lipoprotein (OX.non-HDL %) with a significant reduction in the percentage of oxidized high-density lipoprotein (OX.HDL %) as compared to the controls. The disturbance in the oxidant / antioxidant balance happened despite the treatment and blood pressure control showing different pictures with different modalities of treatment, being the best with the captopril.

Conclusion: Hypertensives on different modalities of therapy experienced dyslipidemia, (High triglycerides and small dense LDL particles) and oxidative stress presented by changes in the percents of oxidized lipoproteins especially in those on NPAHT.

The suggested mechanisms underlying these events are discussed.

Keywords: hypertension, lipid peroxidation, ox-HDL, captopril, atenolol

IRAQI J MED SCI, 2007; VOL.5(3):57-64

Introduction
Hypertension (HTN) is considered a major health problem that emerges from the wide occurrence of its cardiovascular complications. Recent studies indicate that oxidative stress mediated by increased level of reactive oxygen species has a causative role in the pathogenesis of cardiovascular disease (CVDs) such as atherosclerosis and HTN, diabetes (particularly in patients with angiopathy), hyperlipidaemia and acutely after myocardial infarction and stroke. The antioxidant and lipid peroxidation products are being extensively studied because of their potential importance.
and pathogenetic role in several non-communicable diseases like CVDs and cancer, but the data on HTN is scanty (4). The present study was undertaken to elucidate the role of oxidative stress, a lipid peroxidation on essential hypertension with the emphasis on the effect of different treatment modalities on these parameters.

**Subjects & Methods:**

**A- Subjects:**

The study was conducted on 69 patients aged 30-70 years (mean age = 50.52 ± 8.71 years) with essential hypertension (HTN) attending the medical consultant-clinic at Al-Kadhumia Teaching Hospital, for evaluation of newly diagnosed HTN or re-evaluation of long-standing HTN. The treated hypertensives were either using pharmacological antihypertensive therapy (PAHT) for a period ranging from two months to nineteen years, or not using PAHT for a period ranging from six months to five years. They were attending the clinic for assessment of control and, if necessary, modulation of therapy. The newly diagnosed patients were first discovered to have HTN during their preliminary attendance to the private clinics few weeks (1-4) before their current visit. During this interval, they had not taken any antihypertensive, with their latest attendance to the consultation clinic was for confirmation of diagnosis and, if HTN persisted, commencement of therapy.

Any patient with other medical illnesses that may have an effect on the measured parameters was excluded from the study, as cardiac, hepatic, endocrine, metabolic diseases, smoking and alcoholism. None of the female patients were pregnant nor on contraceptive pills. Details of clinical state were taken from each subject. Depending on the modality of AHT, the patients were divided into three groups:

1- **hypertensives on atenolol:** They were 27 hypertensive patients on β-blocker (atenolol 50-100 mg/day), age range 34-70 years (mean age = 51.33 ± 8.81 year).

2- **hypertensives on captopril:** They were twenty-seven hypertensive patients on ACE inhibitor (captopril 25-150 mg/day), age range 30-65 year (mean age = 50.11 ± 8.53 year).

3- **antihypertensives on no pharmacological antihypertensive therapy (NPHT):**

Fifteen hypertensive patients had no pharmacological interference, with age range of 32-64 years (mean age = 49.8 ± 9.33).

**Control group:**

Forty-five apparently healthy subjects were involved as a control group with matching age and sex to the patient group (mean age was 46.04 ± 9.43).

None of them were alcoholic, or on any drug that may interfere with the results of the study. Pregnant females and those on contraceptive pills were excluded.

**B- Blood Specimens**

Ten milliliters of venous blood were drawn from each patient and control after 12 hours fast. The samples were transferred into clean plane tube, left at room temperature for 15 minutes for clotting, centrifuged, and then serum was separated and divided into 2 parts:

1- for measuring the glucose, urea & creatinine (these were measured at the same day of collection in the laborotaries of Al- Kadhumia Teaching Hospital for TG, TC, HDL-C, and LDL-C. the tubes were stored at 4°C for no longer than
seven days\(^5\). For measuring the total level of oxidized lipids (measured as total malodialdehyde MDA) and specific levels of oxidized HDL (measured as HDL-MDA). The tubes were stored at \(-20^\circ C\) until analysis, which was done within one month after collection\(^6\).

**C- Methods:**

The thiobarbituric acid (TBA) method of Buege & Aust (1978)\(^5\) was used to measure serum MDA, which reacts with TBA to give a pink color that is read at 535 nm. The MDA concentrations were calculated using the molar extinction coefficient of \(1.5\times10^5\).

The procedure was also conducted on the fractionated specimens to obtained levels of oxidized HDL. Oxidized-non-HDL (oxidized LDL-VLDL) was obtained by subtracting the value of oxidized HDL from the total oxidized lipids i.e. Oxidized-non-HDL = total MDA – oxidized HDL.

**Protein in urine** was detected by 30% trichloroacetic acid precipitation method\(^6\) to exclude any patient with proteinuria.

**Results:**

**Lipid peroxides profile:**

The results of total lipid peroxides, (expressed as s. MDA) and oxidized lipid fractions, which included ox. HDL (expressed as HDL-MDA) and ox.non-HDL are described as absolute values (for s. MDA) and as percentages from the total (for oxidized lipid fractions). These results are shown in Table (3-1).

Serum MDA was highly significantly increased in HTV patients on atenolol (ATE) and captopril (CAP) \((P=10^{-6} \& 10^{-5} \text{ respectively})\) when compared to controls and was also significantly increased in HTV on non-pharmacological antihypertensive therapy (NPAHT) \((P=0.03)\) as compared to the controls. There was, also a significant variation between hypertensive groups when compared with each other (Table 1).

Hypertensives on atenelol & NPAHT caused a significant reduction of OX.HDL\% fraction \((P=0.05 \& 10^{-4} \text{ respectively})\); however, HTV on captopril had insignificant reduction in this fraction \((P=0.4)\) when all groups were compared with the controls. Also, there was a significant variation between hypertensive groups when compared with each other (Table 1).

In contrast to OX.HDL\%, hypertensives on atenolol and on NPAHT had a significant elevation of OX.non-HDL\% \((P=0.05, 10^{-4} \text{ respectively})\); however, hypertensives on captopril had insignificant elevation in this fraction \((P=0.45)\) when all groups were compared with controls. There was a significant variation between hypertensive groups when compared to each other \((P=10^{-3})\) (Table 1).

**Serum lipid profile:**

Serum triglyceride (TG), total cholesterol (TC), high density lipoprotein cholesterol (HDL-C), low density lipoprotein cholesterol (LDL-C), atherogenic index (expressed as LDL-C/HDL-C) and LDL size index (expressed as TG/HDL-C) are shown in Table 2.
Table (1): lipid peroxides and oxidized lipoprotein fractions (mean ± SD) in different groups of hypertensive patients and control group.

Discussion:
The results showed that, oxidative stress increases in hypertensive (HTV) patients regardless the modality of treatment, this is clear from the highly significant elevation of serum MDA level and is in agreement with the results of previous reports (7,8).

This elevation in serum MDA may be due to the association of high blood pressure (BP) with a loss of balance between pro-oxidation and anti-oxidation, energy depletion, and accelerated aging in the target organs, such as heart, kidney and brain (9).

Essential HTV patients are more prone than the normotensive subjects to oxidative stress; because of an increased production of reactive oxygen metabolites and of lipid peroxidation products (10), something that was reported to be frequent among such patients. This may results in a poor control of BP and hence progression of target tissue damage (11). The latter will be reflected by an elevation in serum MDA as an index of oxidative stress; however, the presence of undesirable side effects of these drugs might contribute to some rise in serum MDA, this contribution varies from one type of therapy to another. Beta-adrenergic blockers were reported to increase cholesterol side effects besides the central nervous system effects. However, ACE inhibitors have fewer side effects in general (12).

It remains to be determined whether these events are simply consequences of tissue damage or strictly involved in primary pathogenic mechanism of HTN. Therefore, a study of oxidant and antioxidant factors seems to be useful in HTV patients in order to evaluate oxidative stress and to correct, if possible, the observed abnormalities with dietetic or pharmacological therapy (13).

The term “oxidized non-HDL” refers to the oxidized form of VLDL and LDL. The oxidation of LDL appears to be involved in the development of atherosclerosis. The oxidation of LDL leads to alteration of the LDL apolipoprotein B (apoB) recognition site and in the unregulated uptake of LDL by the macrophages via the scavenger receptor. The subsequent accumulation of cholesterol-loaded macrophages (foam cells) in the sub-endothelium

*Student t-test was done between each HTV group and control groups.

ATE : Atenelol , CAP : captopril
leads to the accumulation of fatty streaks and atherosclerotic plaques (14).

In the in-vitro studies, OX-.LDL was shown to be taken up by the macrophages three to ten times than native LDL (15). Furthermore, OX.LDL is chemotactic for circulating monocytes, while decreasing the motility of tissue macrophages (15,16); and also stimulates the release of growth factors and cytokines by endothelial cells to further stimulates monocyte migration. The oxidized form of LDL is known to be cytotoxic to endothelial cells and may cause an autoimmune type of response against endothelial cells. Also OX.LDL inhibits endothelial-derived relaxing factor (EDRF)-mediated vasorelaxation. EDRF appears to be crucial in maintaining coronary vasodilation and its activity is impaired in hypercholesterolaemia and atherosclerosis (15,16).

According to the results of the current study, there was a significant elevation of OX.non-HDL in HTV groups on atenolol (ATE) and those on no pharmacological antihypertensive therapy (NPAHT) as compared with the controls, the NPAHT being the highest. This suggests that those patients are more prone to have atherosclerotic changes than those receiving medications with the presence of smaller forms of LDL particles (as evident from higher TG / HDLc molar ratio). On the other hand hypertensives on atenolol have significantly higher level of OX.non-HDL than patients on captopril, who showed insignificant increase in this fraction as compared to the controls; this is due to the fact that ACE inhibitors inhibit LDL oxidation and attenuate atherosclerosis independent of lowering BP and this may due to direct inhibition of angiotensin II-dependent effects (17).

As concerning oxidized HDL, it has been postulated that HDL has a protective effect against the formation of OX.LDL, and one of the mechanisms is mass transfer of lipid peroxidation products between lipoproteins (18) (i.e. from LDL to HDL) forming OX.HDL which was markedly reduced in the present HTV, mostly those on no medications on the expense of the increase in the atherogenic form of LDL (OX.LDL).

Percentages of OX.HDL were also reduced in HTV people receiving medications but to a lesser extent and with a variable degree depending on the antioxidant properties of the antihypertensive drug being only slightly reduced in those on captopril. This indicates that untreated HTV were more prone to have atherosclerosis than those receiving medications. Also, HTV on atenolol had a higher reduction in percentages of OX.HDL than those on captopril this reveals the antiatherogenic protective effect of captopril against vasculopathy.

The findings of this study, suggest that the studied drugs (atenolol & captopril), in addition to their antihypertensive effect that control Blood pressure, possess antioxidant properties that make them an important means to retard the progression of atherosclerosis in hypertensive peoples.

The antioxidant property of captopril was well evident through the results of MDA, OX.non-HDL and OX.HDL (when results of the above parameters were compared with the healthy controls and other hypertensive groups), and it exceeds that of atenolol and probably overcome its antihypertensive effect (19). Reported increased nitric oxide (NO)
production, decreased production of thiobarbiturate reactive substances and enhancement of endogenous antioxidant defense during the treatment with captopril. Therefore, the goal of appropriate antihypertensives should not be restricted to achieving normotensive BP values, but should also aim to reduce other risk factors of cardiovascular diseases\(^{(20)}\). Further improvement in cardiovascular risk can be obtained only with a comprehensive approach to hypertensive patients, including dietary and lifestyle modifications and the use of antihypertensive drugs with beneficial effects on lipid metabolism. It has to be noted that, some of these drugs have divergent effects on lipid metabolism. While \(\beta\)-blockers decrease HDL-C and increase triglyceride (TG), ACE inhibitors do not affect lipid metabolism \(^{(20, 21)}\).

In the present study, There was also a significant increase in s.TG and s.TC level in the untreated hypertensives. While there was no significant changes in s.HDL-C and s.LDL-C levels, these results are consistent with the fact that untreated HTN has been shown to be associated with a significant elevation in s.TG and s.TC levels\(^{(22)}\). The results of this study and others support the hypothesis that hyperlipoproteinaemia is often observed in untreated hypertensives patients\(^{(23)}\), and when HTN is associated with high plasma lipid levels, it is an atherosclerogenic factor of greater clinical significance causing CVDs\(^{(24)}\).

However, the role of TG in CVD is a controversial subject. Many epidemiological trials do not identify hypertriglyceridaemia as an independent risk factor when the cholesterol and, in particular the HDL-C level, are taken into consideration. Nevertheless, these results must be interpreted with caution as hypertriglyceridaemia represent a very heterogeneous entity which is closely related to many factors that may affect coronary risk (hypertension, insulin resistance, sedentariness, and even tobacco consumption). Therefore, hypertriglyceridaemia and hypo-HDLaemia may be the results of the same primary abnormality, as the HDL-C level is more stable, it is the parameter, which will be identified as a protective factor in epidemiological trials\(^{(25)}\).

PREVALENCE OF PARKINSON’S DISEASE IN AL-KADHIYUMIA DISTRICT (BAGHDAD CITY): COMMUNITY-BASED STUDY

A. Mutalib A. Kareem FRCP, Amjad D. Niazi PhD, A.F. Abdullah MBChB

Abstract:
Background: Parkinson’s disease is a chronic neurodegenerative disorder affects mostly people above 40ys. Studying its prevalence is crucial for health public planning especially as worldwide communities are getting older. There are some worldwide variations in the estimated prevalence rates and the figures are unknown in our country.

Objective: To estimate the prevalence of Parkinson’s disease in Al-Kadhiymia district.

Methods: Community-based study was conducted as cross-sectional survey on random sample of the population of the district. Suspected cases of Parkinson’s disease identified during home visits were referred to the neurological department at the University Hospital of Iraqi Medical College in order to confirm the diagnosis of the senior neurologist. Diagnosis is made by identifying at least two cardinal features of the disease (resting tremor, bradykinesia, rigidity and postural instability) in the absence of signs of secondary Parkinsonism.

Results: 25 cases of Parkinson’s disease collected from a random sample of 22,988 individuals (13 were males, 23 were females. 6 lived in rural areas and 19 in urban). Three cases (12%) were newly diagnosed. Tremor was the predominant symptom of onset (80%). 19 cases had bilateral involvement of the disease, in spite of the unilateral onset of all cases. The crude prevalence rate was 108.75 per 10^5 populations. Age adjusted prevalence rates showed constant increase with age. Gender-adjusted prevalence rates were calculated for male 114/10^5 populations and for 103/10^5 populations. Residency-adjusted prevalence rates were 114, 94.3 per 10^5 populations for urban and rural living respectively.

Conclusion: Prevalence rate of Parkinson’s disease is just lower than the figures in Europe and North America, but higher than those of Africa and China. It increases constantly with increasing age. There was no significant gender or rural difference in the prevalence rates. The prevalence figure can be applied to the population of Baghdad City because of the similar population structure and characteristics to those of Al-Kadhiymia district.

Keywords: Parkinson disease, prevalence, Baghdad, cross sectional study

IRAQI J MED SCI, 2006; VOL.5 (2):65-72

Introduction:
Parkinson’s disease (PD) is a progressive neuro-degenerative disorder, which affects the movement or the control of movement including speech and “body language”. Four cardinal signs dominate it: bradykinesia, tremor and rest, rigidity and postural instability. It mostly affects elderly people with overall prevalence of about 1.6 percent in persons over 65 years of age[1].

The disease is chronic and progressive. Its life expectancy increased since the introduction of L-dopa treatment. Other medical therapies and some recent surgical techniques providing continuous improvement of the disease disability[2].

In addition, the population of the world, in general, is growing older because of the improving health services. This gives an indication that PD will affect more people i.e. incidence and prevalence of the disease will continue to rise[1]. These facts indicate that the importance of PD as a
Prevalence of parkinson’s disease in Al-Kadhiymia …. Kareem et al

population health issue is expected to increase in the near future.

The prevalence of PD is studied worldwide with some variations in the figures \[3-33\]. In 1990 worldwide estimated 4 million people were suffering from PD, approximately one million of them in North America \[1,2\].

In Iraq, there is no local record about the prevalence of PD or the epidemiological factors that affect it. Therefore, we found that it was necessary to study this subject in order to identify the disease extent and to plan useful measures for health care institutions and personnel.

Patients and Methods:

Area of the study

The area chosen for the study was Al-Kadhiymia district, one of the original regions in Baghdad City (Capital of Iraq). It is located north of Baghdad on the western bank of the Tigris River. The total population of Al-Kadhiymia district is 480686 people, according to the Iraqi population survey of 1997 distributed into 38 sectors in urban area and 16 villages in rural one. It was chosen because of:

1. Large number of its population,
2. Its inhabitants are of different social classes,
3. Containing both rural and urban areas,
4. Its proximity to the University Hospital.

All individuals involved in the study were asked to take part in it. Their consent was taken while visiting their families at home.

Sample of the study:

A random sample was determined from the general population of the district as follows:

* For urban area: in each sector, 20% of the families were selected randomly and included in the study.
* For rural area: 20% of the families living in villages were randomly selected to be enrolled in the study.

The sample was about 23 000 individuals described as families in order to involve all age groups. The random sample was determined and designed in cooperation with the Central Statistical Organization authorities that provided us with a detailed account on the names, locations and numbers of the selected streets and sectors. These numbers were listed by local authorities, in marks at beginning and end of streets.

Survey:

This is a community-based study, designed as a cross-sectional survey on the general population. A suitable questionnaire was designed \(see\ appendix\) in two parts so that the study was run in two phases:

* Phase 1 (screening phase): Families were interviewed at home. One of the researchers did the interviewing to explain the purpose of the study, ask questions about age and gender of each family member and the presence of any of the following:
  1. Tremor of the hands “Is there any trembling movement of the hands?”
  2. Bradykinesia “Is there any slowness of movement during walking?”
  3. Previous diagnoses of PD “Is there any member who has the diagnoses of PD?”
  4. Use of antiparkinsonian drugs “Is there any one who is taking L-lopa, Trihexyphenidyl or Bromocriptine tablets?”

Any member who had positive answer would be examined to demonstrate the Parkinsonian signs. Patients excluded from further assessment if they had used anti Parkinsonian drugs for other indications (e.g. Bromocriptine for pituitary adenoma or prophylactic treatment with anticholinergic drugs in
association with dopamine antagonists in patients with psychotic disorder.

* Phase 2 (confirmatory phase): All suspected cases of PD were referred to the neurological department of the Al-Kadhimiya Teaching Hospital where history and neurological examination is performed by senior neurologist.

Patients with confirmed diagnosis of PD would be questioned about: the duration of their symptoms, type of onset, drug ingestion (neuroleptics, antidopaminergic), family history of PD or tremor, presence of medical illness, smoking, number of rooms, family members and total years of education (see appendix).

**Diagnosis criteria**

According to the WHO definition [1] PD was diagnosed when the patient had at least 2 of the cardinal signs (resting tremor, bradykinesia, rigidity and postural instability) with no signs of nervous system involvement, such as corticospinal deficit, cerebral dysfunction, conjugate down or lateral gaze impairment, or prominent early automatic nervous system involvement. Patients with drug induced Parkinsonism were excluded.

![Pie Chart](image)

**Figure 1:** The distribution of onset symptoms in patients with Parkinson’s disease

**Statistical analysis**

Our data was computed in Pentium III system using the statistical analysis system (SPSS version 10.0). We calculated the prevalence rates as crude and category specific (age, gender, and residency). The quantitative data were expressed as mean (X) standard deviation (SD). We determined whether differences in prevalence rates were statistically significant or not by student (t) test and chi-square (X^2) test. A probability limit (p value) of <0.05 was considered statistically significant.

**Results:**

The cross-sectional survey started from December 1st 2000 till September 15th, 2001. The total population involved in this study was 22988 individuals, 11645 (50.7%) of them were females and 11334 (49.3%) were males. Individuals living in urban areas were 16646 (72.3%) and in rural ones were 6364 (27.7%). 76 individuals with suspected PD were referred to the Al-Kadhimiya Teaching Hospital, 55 (72.3%) of them responded and 21 did not.

Those who did not respond two of them had written certificate of diagnosis of PD by a senior neurologist, two were bedridden with full certificate of PD confirmed by the neurologist, and for the other a second visit was done for reassessment that revealed exclusion of
Prevalence of parkinson’s disease in Al-Kadhiymia …. Kareem et al

A total number of 25 cases of PD were collected, 13 males (52%) and 12 females (48%). Three cases (12%) were not diagnosed yet by the time of the survey. Those who were referred but not diagnosed as PD, they had benign essential tremor, dementia or cerebrovascular accident.

The crude prevalence rate of PD was **108.75 per 100 000** population. The results of category specific prevalence rates are as follows:

Residency: Table-3 shows the distribution of cases of PD among rural and urban areas. Nineteen cases were living in urban areas (10 males, 9 females) and six cases in rural one (three males, 3 females). There was slight increase in prevalence rate of PD in urban (114.29/10⁵) more than in rural (94.28/10⁵). This difference was of no statistical significance ($p=0.68$).

Onset: The predominant symptom of onset was tremor, which was present in 20 cases (80%), stiffness of the back was the initial symptom in three cases (12%) while bradykinesia was in two cases (8%), as shown in figure-2. All cases had a unilateral onset.

Laterality: The disease was unilateral in six cases (24%), and bilateral in 19 cases (76%). The average duration of the illness in unilateral disease was about half that of bilateral one. This is shown in table-4.

Discussion:

Studies on the prevalence of PD had been conducted in many parts of the world, for example: Australia, New Zealand, Japan, United States, United Kingdom and Iceland. These studies generally relied on record of providers of health services (mainly hospitals and medical practitioners) in the identification of cases. Such maneuvers exclude individuals who failed to seek medical attention for their PD symptoms, as well as those who were improperly diagnosed.

This study was a community-based one where the approach of case finding was to go into the community and screen for patients with PD at home. This approach is more accurate especially in our circumstances where medical records are improperly handled and seeking medical advice is incomplete because of ignorance of symptoms, socio-economic difficulties or disease disability.

This is the first community-based study for PD carried out in our country to estimate prevalence of PD.

We found the crude prevalence of PD in the study population was 108 per 100 000 population. This figure is slightly lower than those reported in Europe and North America: London (193)\textsuperscript{[11]}, Finland (166)\textsuperscript{[4]}, San Morino (152)\textsuperscript{[5]} and Canada (244)\textsuperscript{[6]}. However, it is much higher than African figures: Nigeria (10)\textsuperscript{[7]}, Libya (31)\textsuperscript{[8]}, as well as China (57)\textsuperscript{[9]}.

These differences may be attributed to a different genetic susceptibility in different race\textsuperscript{[10]}. However, other factors should be considered. Different age structures where older age population is more in developed countries may contribute to the higher prevalence rates\textsuperscript{[11]}.

Mores et al\textsuperscript{[12]} found that incidence rates were similar in Asian-American men and in white men. This may be explained by more complete ascertainment than the previous studies. Alternatively, it may reflect a real increase in disease frequency among nonwhite U.S. residents because of increased exposure to an environment factor.

Recent prevalence study on PD was conducted in Taiwan on people of similar ethnic group to Chinese. It revealed a prevalence rate similar to European figures, suggesting that environmental factors might be more important than racial factors in the pathogenesis of PD\textsuperscript{[13]}.

Age: There was a consistent and rapid increase in prevalence PD with increasing age, even in the highest age categories. It increases about 20 times from age group of forty to that of eighty. This finding was similar to other studies\textsuperscript{[4,11,13,33]}. Three cases (12\%) were identified below the age of 50, corresponding to WHO figure\textsuperscript{[1]}.

Although PD is intimately related to aging, it has been demonstrated that its underlying process is distinct from natural aging. There is a marked microglial reaction to neuronal damage in PD that is not seen in normal aging\textsuperscript{[36]}. It may be explained by aging-related factors like chronic exposure to neurotoxicants.

Gender: Prevalence of PD regarding gender distribution is controversial. Some studies show higher prevalence rates in men than women\textsuperscript{[3,4,6,8,19,20,21,22,37]}. Other studies\textsuperscript{[5,10,14,15,24]} found equal gender prevalence. In our study, there was no significant gender difference in the prevalence rate.

Residency: Several studies\textsuperscript{[6,24-26]} indicated that rural living is a significant risk factor for PD. As Gorell study\textsuperscript{[38]} we found no association between rural living and PD. It’s the individual characteristics of rural living like farming, use of well water and exposure to herbicides and insecticides are the factors associated with PS\textsuperscript{[24,25]}. These factors need to be
evaluated in a specific case-control study with larger sample size.

**Characteristics of the disease:** The onset symptom was predominately tremor 80%, while stiffness only 12%. This may be explained, as both stiffness and slowness of movement are manifestations of getting older, so the patients were unaware of them.

Three cases were first diagnosed at the time of study representing 12% of total cases. This is agreed with the assumption of Shrag [3] that 10–20% of all community patients remain undiagnosed.

**Conclusion:**
1. Prevalence of Parkinson’s disease in Al-Kadhimiya district is 108.75 per 100,000 population. This figure is slightly lower than European and American figures but more than in Africa and China.
2. There were no significant gender or residency differences in the prevalence of Parkinson’s disease.
3. The prevalence figure can be applied to the population of Baghdad City because of similar population structure and characteristics to those of Al-Kadhimiya district.

Clinical plus Color Doppler Assessment of Benign and Malignant Breast Diseases
Hikmat Abdul Rasoul Hatam1 FRCS, Bashar A. Abdul Hassan2 FIBMS.

Abstract:
Background: Tumor growth and metastases require the development of new vessels (angiogenesis), and the extent of angiogenesis predicts metastases and correlate with early death. Recently developed color Doppler mapping can detect the tumor flow signals in breast cancer and help to distinguish it from benign lesions.

Objective: Evaluation of differences between the blood supply in benign and malignant breast lesions by the use of color Doppler image assessment of the lesions vascularity.

Method: Clinical assessment, ultrasound examination and color Doppler mapping were done for 83 female patients with breast lesions. The following flow data analyses were undertaken; presence or absence of color Doppler signal, number of blood vessels, architectural arrangement and the maximum systolic velocity of blood vessels in the lesions and around it.

Results: Histopathological reveals that 21 cases had carcinoma of the breast and 62 had benign lesions. 27 patients provisionally diagnosed as having malignant lesions; of them 15 cases were truly malignant (sensitivity: 71.5%) and 56 benign one; of them 50 lesions were truly benign (specificity: 80.6%). An increasing number of blood vessels found in malignant lesions; (85.7%) showed more than 3 vessels in a given lesion, while this figure found only in (8%) of benign lesions. For a cutoff of more than 3 vessels sensitivity and specificity are (85.7%), (91.9%) subsequently.

Architectural differences in the form of penetrating central neoplastic vessels were present in 18 (85.7%) of the malignant lesions with sensitivity (90.4%), while only in 3 (6.1%) of the benign lesions with specificity (93.8%).

The maximum systolic velocity of tumor vessels showed an increasing velocity in malignant lesions, for a cutoff more than 15 cm/s the sensitivity was (90.4%) and specificity was (91.8%).

Combination of the three parameters gave (90.4%) sensitivity and (96.7%) specificity.

Conclusion: Color Doppler imaging considered as an adjuvant primary investigation tool in addition to the ultrasound examination in improving differential diagnosis of breast lesion.

Keywords: Color Doppler, Breast diseases, Benign, Malignant.

IRAQI J MED SCI, 2007; VOL. 5 (3): 73-80

Introduction:
Although an accurate history and clinical examination are important methods of detecting breast diseases, imaging procedure such as mammography and ultrasound which play an established role in the investigation of breast masses (1), these methods are limited by their inability to answer questions about the likely growth potential of suspicious breast masses (2). Since advent of color Doppler sonography, however, the visualization of blood flow deep within the breast becomes practicable (3).

By demonstrating blood vessel architecture and measuring blood flow parameters, the color Doppler technique has the potential to determine the tumors tendency towards malignancy (4).

Doppler flow in malignant breast lesions is enhanced, so Doppler flow signal can be used to detect increased flow and may further distinguish benign from malignant lesions. Malignant lesions produce signals of high frequency and amplitude with continuous flow through diastole (5).
Vasculature of neoplasm (Tumor angiogenesis) is one of the most important factors other than cell kinetics modifies the rate of tumor growth. Tumor cannot enlarge beyond 1-2 mm in diameter unless they are vascularized, presumably the 1-2 mm zone represent maximal distance across which oxygen and nutrient can diffuse from blood vessel. Neovascularization has dual effect on tumor growth; perfusion supplies nutrients and oxygen, and newly formed endothelial cell stimulate the growth of adjacent cells by secreting polypeptides such as insulin like growth factor, PDGF (Platelet Derived Growth Factor), IL-1 (6).

Angiogenesis is a request not only for continued tumor growth; the tumor cells cannot metastasis with out access to vasculature. Several studies have revealed a correlation between the extent of angiogenesis (micro-vessel density) and probability of metastasis in melanomas, lung, colon, prostate, and specifically breast cancers, so vessel density has proven to be significant prognostic indicator (6).

In addition the architecture of tumor’s vascular supply is a reflection of it’s propensity towards malignancy, and is a marker of tumor aggressiveness and correlated with an over all poor prognosis (7).

Tumor vessels grow to produce a disorderly tangle and random orientations (4). However, because of focal area of narrowing and dilatation within tumor vessels, focal area of high systolic velocity results (8).

Tumor cells in lymph node also stimulate angiogenesis in the surrounded tissue to invade enlarged lymph node resulting in an extralinear vessel leading to abnormal architectural vasculature that can be assessed by color Doppler for accurate staging of lymph nodes (5).

Color Doppler flow mapping; two dimensional color Doppler flow mapping system which none invasively maps intra organ blood flow in that previously could only be done with angiography

Positive Doppler shift (flow toward the transducer) displays in shades of red through orange to yellow where as negative shifts (flow away from the transducer) are displayed in blue to blue green (10).

Materials and Methods:

Eighty-three female patients with breast lesions included in this prospective study were presented to the consultant unit. After a detailed history and thorough physical examination, patients were assessed by imaging and laboratory investigations.

All patients were examined sonographically, then color Doppler image studies were performed using available KRETZ Techink voluson 530 OD machine versa pro utilizing 7.5 MHz linear array prop.

After full examination of breast and axilla, the mass identified and kept with field of color Doppler flow mapping.

The following parameters were assessed
1. Presence or absence of color Doppler signal and counting the total number of blood vessels in and adjacent to the lesion (mass).
2. Vascular architecture in relation to the lesion (mass), vessels were classified as either peripheral as in (Fig. 1) or central penetrating (neoplastic vessel) as in (Fig. 2).
3. Maximal systolic velocity (of that lesion or mass) measured from the time velocity diagram, (Fig.3), (Fig.4).

Color Doppler flow mapping of axillary Lymph Nodes were done for patients with palpable enlarged axillary Lymph Nodes, any abnormal signals were recorded as in (Fig. 5).

Biopsy examinations were done for the lesions after appropriate surgical management depending on clinical, imaging, and cytological examinations.

Statistical Analysis:

Sensitivity measures fraction of patients with malignant breast disease detected by the test under study.

Specificity measures the fraction of patients correctly identified as having
benign breast lesions and proved by histopathology.

Figure 1: Peripheral feeding vessel (red spot) out side the tumor.

Figure 2: Central penetrating neoplastic vessel (red line) within the nidus of tumor.
Figure 3: Maximal systolic velocity in malignant breast lesion.

Figure 4: Maximal systolic velocity in benign breast lesion.
Of the eighty female patients included in this study, histopathological findings showed that 62 samples were benign lesions and 21 were malignant.

Based on the clinical findings, 56 patients provisionally diagnosed as having benign lesions, of them 50 patients were truly benign by histopathological examination, whereas 27 patients provisionally diagnosed as having malignant lesions; 15 patients of them proved malignant by histopathology, Sensitivity 71.5%, Specificity 80.6%. Malignant lesions it was central (neoplastic) vessel in 19 lesions & Lesions; (1 was scirrhous carcinoma & 1 well differentiated ductal carcinoma).

The 49 vascular benign lesions detected by color Doppler image showed central neoplastic vessels in only 3 lesions (1 hyperplasia, 1 giant fibroadenoma & 1 chronic abscess).

Sensitivity was (90.4%), while specificity was (93.8%).

3. Maximal systolic velocity; of the lesions blood flow measured by time velocity scale in centimeters per second (Figure 7).

For a cutoff more than 15 cm/s; sensitivity was (90.4 %), while specificity was (91.8 %).

Figure 5: Color Doppler imaging of an enlarged left axillary LN in patient with CA breast showed a central vessel (blue spot).

**RESULTS**

Three female patients included in this study, histopathological findings showed that 62 samples were benign lesions and 21 were malignant.

Based on the clinical findings, 56 patients provisionally diagnosed as having benign lesions, of them 50 patients were truly benign by histopathological examination, whereas 27 patients provisionally diagnosed as having malignant lesions; 15 patients of them proved malignant by histopathology, **Sensitivity** 71.5%, **Specificity** 80.6%.

Malignant lesions it was central (neoplastic) vessel in 19 lesions & Lesions; (1 was scirrhous carcinoma & 1 well differentiated ductal carcinoma).

The 49 vascular benign lesions detected by color Doppler image showed central neoplastic vessels in only 3 lesions (1 hyperplasia, 1 giant fibroadenoma & 1 chronic abscess).

Sensitivity was (90.4%), while specificity was (93.8%).

**Color Doppler image:**

1. **Number of blood vessels:** in all malignant lesions color Doppler signals were detected, in 18 cases the number of blood vessels were >3, other cases showed <3 vessels, while in benign group; signals were detected in 49 cases, only 5 of them have >3 vessels (Figure 6).

For a cut off of more than 3 vessels, the sensitivity for detecting cases with carcinoma was (85.7%) while specificity was (91.9%).

2. **Vascular architecture:** in peripheral (curvilinear) in the remaining 2 lesions.

**Color Doppler imaging of axillary lymph nodes:** in 16 patients had palpable axillary lymph nodes, signals were positive in 9 cases, all of them were malignant on histological
examination, in the other 7 cases; signals were negative, of them 4 benign and 3 malignant cases, so; Sensitivity 75%, Specificity 100%.

Figure 6: Distribution of the lesions according to the number of blood vessels.

Figure 7: Distribution of lesions according to the maximum systolic velocity cm/s.

Discussion
According to the clinical evaluation, our provisional diagnosis revealed a sensitivity (71.6%) and specificity (80.5%), which is comparable to the results of a study done in Baghdad Teaching Hospital in 2001; sensitivity (73.68%) and specificity (89.4%) \(^{(11)}\).

Color Doppler examination is diagnostically useful in identifying solid nature of markedly hypo-echoic malignant lesion, however the vascularity is highly increased in cases of mastitis where patient management should not be based on Doppler findings, in addition Doppler artifact can cause false positive results and this must be taken into consideration;
movement of the transducer or the patient, breathing, heart motion and fluid movement in a cyst, microcalcification must be differentiated from true signals caused by blood cells movement (\textsuperscript{12}).

In our study the detected signals were demonstrated in all malignant masses (100%), and majority (79%) of benign lesions, in a study done by Wei-Jei Lee et al., in National Taiwan Hospital (department of surgery) showed that signals were detected in (92%) of malignant one and (54%) of benign lesions (\textsuperscript{13}). Other study showed absence of vascularity only in (4%) of malignant lesions (\textsuperscript{12}).

In this study more than three blood vessels were found in (85.7%) of malignant lesions and only (8%) of benign cases, in comparison with a study (\textsuperscript{12}); (89%) of malignant tumor showed more than three vessels.

McNicholas et al., evaluate the number of blood vessels; they found that three and more blood vessels present in (83%), (46%) of malignant and benign lesions subsequently (\textsuperscript{14}).

We found that a cut off more than three tumor vessels, the sensitivity, specificity were (85.7%) and (91.9%) subsequently, compared with literature; they were (89%) and (92%) subsequently (\textsuperscript{12}).

Regarding the vascular architecture, a centrally penetrating vessel (neoplastic vessel) is a character of malignancy, it was found in (90.5%), (6.1%) of malignant and benign lesions subsequently. Wei-Jei Lee found that signal was central in 83% of malignant lesions, while all benign lesions show only peripheral signals (\textsuperscript{13}).

The maximal systolic velocity is recommended as the best parameter in the differentiation of benign from malignant tumor by Dock (\textsuperscript{14}), they suggest that systolic peak flow more than 20 cm/s is the best cut off value. In our study; a peak flow of more than 15 cm/s found in 19 of 21 malignant lesions (sensitivity 90.4%, specificity 91.8). Wei-Jei lee found that for a systolic peak of more than 15 cm/s 26 of 28 (93%) patients had malignant lesion (\textsuperscript{13}). Other study done by Madjar et al., they found that a cut off value more than 15 cm/s has (86%), (91%) sensitivity and specificity respectively (\textsuperscript{15}).

The number of blood vessels detected by color flow mapping has been identified as the easiest parameter for describing tumor vascularity, but diagnostically it is not entirely reliable as the flow velocity (\textsuperscript{16}).

In cases with positive signals axillary lymph nodes; the original primary lesions had a maximal systolic velocity > 20cm/sec; including 3 cases with tumor size about 3 cm, indicating that high velocity is associated with early metastatic potential rather than the size of primary (\textsuperscript{12}).

**Conclusion:**
Color Doppler examination is a complementary tools to the clinical evaluation and other investigations especially the ultrasound.

Based on vascular architecture, number of blood vessels, systolic velocity within the lesions, a provisional diagnoses whether a lesion is benign or malignant, could be suggested with high accuracy.

The presence of high flow tumor signal in early breast carcinoma is significantly associated with the presence of axillary lymph nodes metastases.

**Recommendation:**
Standardization of the color Doppler examination technique and equipment parameter is essential for vascularity assessment of tumors.

Ovarian tissue transplantation: A new method and site for induction of folliculogenesis in mice as a model for human female

Muhammad-Baqir M-R. Fakhrildin PhD., Fuoad K. Al-Rubayae MDM Sc., Ibtissam J. Sodani BVM

Abstract:
Background: Ovarian tissue transplantation is a new method of restoring fertility to women whose ovaries are not functioning normally. Young women who undergo chemotherapy or radiotherapy for cancer face serious consequences to their reproductive health and severely affect the ovarian follicular store, especially.

Objective: the aim of this study was to demonstrate induction of the folliculogenesis from ovarian tissue (OT) transplanted under kidney capsule in the presence or absence of gonadotropins support.

Materials and Methods: Forty-eight healthy female mice were anesthetized and abdominal cavity is open. From one side of the body, small piece (~1 X 1 X 1 mm) of OT was transplanted to the subcapsular membrane of kidney at another side, and surgical operation is closed. Then, female mice were classified into three groups according to the time of gonadotropins injection. Group 1: mice injected with sterile normal saline (control group). Group 2: mice injected with gonadotropins directly for four days. Group 3: mice injected with gonadotropins for four days after eight days of surgical operation. Follicular growth, quality of retrieved ova and histological changes for transplanted OT were assessed.

Results: In general, no deletion for transplanted OT pieces and no side effects post-operation on mice of all groups were recorded. Best follicular growth of transplanted OT was achieved for groups 1 and 2. Graafian follicles were obtained from transplanted OT of group-2, and less degree for group-1. However, least degree for follicular growth of transplanted OT was reported for group-3 as compared to other groups. Immature and mature oocytes with corona and cumulus cells collected by squashing of transplanted OT.

Conclusions: The present data demonstrate that the ovarian tissue transplantation is possible to undergo follicular growth subcapsular of the kidney. Also, physiology of the body supports the ovarian follicular growth in another site other than normal position. Further studies are recommended on in vitro maturation and fertilization of retrieved ova and embryo transfer.

Keywords: Mice, Ovary, Transplantation, Folliculogenesis, Gonadotropin.

Introduction: Therapeutic advances in the treatment of infertility are leading to improved survival and cure. One problem is that exposure of ovaries and uterus to radiotherapy and chemotherapy in childhood and during the reproductive years predisposes to ovarian failure and permanent uterine damage [1,2]. In addition, a significant number of women experience early menopause due to oophorectomy performed for benign indications [3]. Ovarian tissue transplantation (OTT) has been practiced for over a decade, mainly for experimental purposes. It is now being considered as a potential strategy for preserving fertility in young patients. These strategies have been demonstrated...
Ovarian tissue transplantation in mice… Muhammed-Baqir M., Fakhrildin et al.

in animal models and are now undergoing clinical testing [4,5]. It was suggested that the OTT is a new method of restoring fertility to women whose ovaries are not functioning normally. However, after OTT, follicular development and restoration of hormone secretion have been observed in animal and human studies [6]. It was reported “if ovarian transplantation is proven to be safe and effective in humans, fertility preservation might become readily available for young women who need to delay childbearing for medical or social reasons” [2].

A promising field with respect to preservation of gonadal function and fertility is ovarian cortex transplantation. The ability of ovarian allografts to restore fertility has been demonstrated in several species. Furthermore, OTT was achieved within several sites of the body [7]. In recent years, a resurgence in the field of human ovarian transplantation has occurred, with several teams reporting sporadic cases of both fresh and cryopreserved OTT in different clinical scenarios [8]. Therefore, the aim of this study was to demonstrate induction of the follicular development from ovarian tissue transplanted under capsule of the kidney in the presence or absence of gonadotropins support.

Materials and Methods:

1. Animals

Forty-eight healthy adult female mice of Swiss albino strain (age: 8-10 weeks; weight: 25-28 g) were obtained from the animal house at IVF Institute of Embryo Research and Infertility Treatment / Al-Nahrain University and used in this study. Female mice were kept under suitable environmental conditions such as the room temperature was maintained at 24 ± 2 °C and exposed to 14-hour day light program. Tap water and food in the form of pellet were accessible freely, Ad libitum, to the animals.

2. Ovarian tissue transplantation (OTT) technique

After induction of general anesthesia with intraperitoneal (IP) injection of 100 µL of sodium pentobarbital (Nembutal, Sanofi, France) diluted 1:4 in normal saline. The procedure of OTT used was modified from the method of Gosden et al. [9]. Abdominal cavity of female mouse was opened and small pieces of OT cortex (~1 X 1 X 1 mm) were taken from right ovary. The left kidney was exteriorized and small hole torn in the kidney capsule using fine forceps. Only, one piece of OT was transplanted under capsule of left kidney. Finally, abdominal cavity was closed and Aerospray (Chloranfenical, Calier Laboratories, Spain) and Agrsunt (Sulphanilamide, Agropharm Limited Co., Bucks, UK) were used to cover the wound and prevent microbial infection and inflammation. Then female mouse was placed in clean cage for monitoring and special cure until reversed from anesthesia.

3. Experimental design and ovarian stimulation program

Forty-eight female mice were conducted surgical operation for OTT and randomly divided into three groups according to time of gonadotropins injection. Group-1 (G-1; control group) females injected with 0.1 ml normal saline for four days. Group-2 (G-2) females injected with gonadotropins for four days program post-surgical operation directly. Group-3 (G-3) females injected with gonadotropins for four days program after eight days of OTT and surgical operation. Ovarian stimulation program involves IP injections 5 IU/day FSH (Gonal-F, Serono, Italy) for first three days and 5 IU hCG (Profasi, Serono, Italy) at forth day. Pieces of transplanted OT were recovered after 7-8 hours of last injection for either histological processing and examination or ova retrieval and classification.

4. Histological examination and ovarian follicles assessment

Upon the completion of ovarian stimulation program, six mice were killed by cervical dislocation and the pieces of transplanted OT were recovered and
placed in Bouin's fixative for at least 24 hour. Then, dehydrated by series of ethanol alcohol, cleared by xylene, embedded in paraffin wax (melting point 60 °C), serially sectioned at 5 μm thick and stained with Erlich haematoxylin and eosin [10].

The sections were examined under light microscope for assessment of different types of ovarian follicles and corpora lutea. Ovarian follicles were classified as follows: primordial, primary, pre-antral and antral follicles according to presence of flattened epithelial cells, granulosa cells and antral cavity [7,11]. Different types of ovarian follicles were counted under high power microscope.

5. Ova retrieval and classification

After 7-8 hours of last injection for 10 females, each piece of transplanted OT was recovered from subcapsular kidney with high care and washed with Minimum Essential Medium (MEM; Sigma, UK) twice. Then, piece of transplanted OT was minced in small Petri dish within MEM enriched with 20% bovine serum albumin (BSA) by using special fine forceps. Ova were collected and washed within MEM enriched with 10% BSA. After microscopically examination, ova were classified into immature, mature and atretic according to morphological features and presence of 1st polar body [12].

6. Statistical analysis

Data presented as mean ± standard error of mean (SEM). The crude data were statistically analyzed using statistical computerized package SPSS (Statistical package of Social Science, version-12) to compare among different means of groups by application of Chi-square analysis and ANOVA test. A p value of < 0.05 was considered statistically significant.

Results:

The procedure of OTT subcapsular kidney was easy conducted in mice without real difficulties are faced. However, the results of the present study appeared no lose for pieces of transplanted OT subcapsular kidney (Figure 1 A).

Examination the histological changes in transplanted OT (Figure 1 B and C) appeared best results for follicular development in G-2, and this result in regard to number of primordial, primary and antral follicles non significantly (P>0.05) increased as compared to control group (G-1). Meanwhile, significant (P<0.05) differences in the number of pre-antral follicles were noticed between G-2 and G-1 (Table 1). From the same table, the number of all types of ovarian follicles for G-3 revealed significant (P<0.05) reduction as compared to G-2 and G-1.

The results of ova retrieval and classification were presented in the figure (2). The numbers of immature and mature retrieved ova in the G-2 have the best result in the present study (Figure 1 D). Not significant (P>0.05) differences were noticed in the number of immature ova of G-2 when compared to G-1. In contrast, significant (P<0.05) differences in the number of mature ova were reported between G-2 and G-1. Statistically, significant (P<0.05) reduction in the number of immature and mature ova of G-3 as compared to G-2 and G-1. While, no significant (P>0.05) differences in the number of atretic ova among three groups (Figure 2).

Discussion:

Autotransplantation procedures have historically been limited almost exclusively to non-vascular cortex segments grafted to orthotopic or heterotopic locations [13]. It was reported that the human grafts contained large numbers of germ cells about 11000 primordial follicles, an amount that could provide oocytes for a year [14,15]. Here, we described a successful follicular development after ovarian tissue (OT) transplantation (OTT) subcapsular kidney in mice. Figure (1 A) shows the transplanted OT subcapsular kidney in mice. Performance of OTT was easy and has no problems for general health or no side effects on kidney. The same result was mentioned by Bedaiwy et al. [5].
Ovarian transplantation appears to be a relatively simple, novel technique to preserve endocrine function in women undergoing sterilizing cancer therapy or surgery [3,16].

The reproductive outcome of the ovarian transplantation depends on the degree of cell damage inflicted over the transplanted tissues upon harvesting, processing and subsequent transplantation [17]. Furthermore, transplantation of ovarian cortical tissue and hemiovaries gave rise to pregnancies/live birth in sheep [9], mouse intact ovaries [18] and rats [19]. The human trials have shown promising results that have some limitations that require some more research [5,15].

In the present work, female mice were killed after 7-8 hours of last injection for ovarian stimulation program to induce follicular development and maturity of oocytes without spontaneous ovulation (Figure 1 C and D). It was reported low dose of hCG support oocyte maturation, while ovulation needs high dose of hCG and required longer period reach 11-12 hour [20,21]. In our study, best follicular growth at all stages of transplanted OT was noticed in the G-2 whose female mice injected gonadotropins for four days program. However, no significant (P>0.05) differences in regard to primordial, primary and antral follicles were reported between G-2 and control group (G-1).

Our results following OTT in mice confirm the results of previous work carried out by Weissman and his colleagues [7], they reported that the follicular development after using combined gonadotropins, FSH and LH. Although it is not known what gonadotropin dose is required for ovarian follicles stimulation [8]. The current data demonstrated that the pre-antral and antral follicles were produced in G-1 from transplanted OT in spite of absence of exogenous gonadotropin support. We assume that this reflects presence of normal endogenous gonadotropin milieu and considered sufficient for follicular development. A similar finding was previously reported about importance of hypothalamic-pituitary-gonadal function on transplanted OT [22,23].

It was certified that the follicles do not progress beyond the stage of two granulosa cell layers without gonadotropin support [24]. However, different follicles of development were observed in the grafted tissue whereas, prior to grafting, only primordial and primary follicles were present [22]. Moreover, limited length of ovarian function in some human ovarian transplant cases using non vascularized grafts may be partially due to ischemic injury until revascularization occurs [5,25]. From the results of the present study, highly reduction in the number of primordial follicles after OTT combined with major loss of oocytes. Same result was noticed on dramatic reduction in the number of ovarian follicles [16]. Approximately 50% of the primordial follicle population survives in isologous grafts in mice [26].

From the results of this study, it is clear that the number of antral follicles is too little, which may be as a result of environmental and site effects on transplanted OT. Weissmen et al. [7] believed that the kidney capsules are unlikely to be able to support complete human preovulatory follicular development. Although, they mentioned that the OT under the kidney capsule has been shown to develop apparently normal antral follicles. However, it was reported that the follicular development from transplanted OT less than the normal physiologically status [27].

The results of the present study appeared that the number of pre-antral follicles for G-2 was significantly (P<0.05) increased as compared to G-1 and G-3. Also, all types of ovarian follicles and immature and mature ova for G-3 were decreased significantly (P<0.05) when compared to G-1 and G-2. The reduction in the number of ovarian follicles may be
as a result of follicular atresia due to ischemia and apoptosis of primordial and primary follicles, especially \[28\]. Whether an ischemic insult of the ovarian tissues is associated with comparable alterations in special molecules is still unknown \[17,29\]. It was known that atretic follicles may reflect the preexisting atretic changes instead of the effect of OTT \[5\]. Also, it was certified that an important technical limitation of cortical grafting, whether orthotopic or heterotopic, is the potential for follicle atresia during the period of ischemia \[2\].

The number of immature ova retrieved from transplanted OT for G-2 was observed non significantly (P>0.05) increased as compared to control group (G-1). Functioning of the graft will be dependent on the initial pool of primordial follicles, the fraction of follicles surviving the grafting procedure, and the local conditions that affect the resting pool of follicles and the fraction of follicles that is recruited from the pool \[15\]. Knowing that every oocyte reaches full maturity after a fixed timespan and considering the inherent asynchrony in follicle recruitment from the reserve in women, the precise detection of the stage of oocyte maturation becomes an absolute requirement for normal fertilization and embryo development \[30\].

Results of this study appeared that the number of mature ova for G-2 was significantly (P<0.05) increased when compared to G-1 and G-3. Also, significant (P<0.05) reduction was reported in the number of mature ova for G-3 as compared to G-1. The possible explanations for this result are: use of four days ovarian stimulation program causes an increased folliculogenesis and oocytes maturity, but the timing start of this program for G-3 may be reduce outcome and efficiency of transplanted OT as far as from process of OTT. Same result was mentioned by Silber et al. \[2\] who reported that the heterotrophic grafts of monkey cortical tissue can generate mature oocytes for IVF. Moreover, several alterations will obviously interfere with the availability of nutrients, hormones and oxygen, which are all essential to obtaining a developmentally competent oocyte \[16,27\].

Non significant (P>0.05) differences in the number of atretic ova was assessed among three groups of this study. This result may be partially due to technical method for OT recovery and/or retrieval of oocytes. Same result was mentioned by Smitz \[15\] who reported that the transplant site might it self influence follicle recruitment and atretia. Furthermore, presence of atretic and/or abnormal oocytes, in the present study, may be reflecting wide range of fluctuation of gonadotropins and/or inadequate exposure to gonadotropins which led to abnormal follicular development and subsequently produce abnormal and atretic oocytes. This result is in agreement with results of several investigators \[16,18,27\]. In contrast, it was mentioned that the elevation level of FSH produces high numbers of abnormal and atretic oocytes \[31\].

Therefore, the present data demonstrate that the transplantation of ovarian tissue is possible to undergo follicular growth subcapsular of the kidney. Also, physiology of the body supports the follicular development in another site other than normal position. Further studies are recommended on in vitro maturation and fertilization of retrieved ova and embryo transfer.

Study of rubella antibody levels among mothers and their newborn babies following normal delivery versus mothers and their newborn babies following cesarean section

Enas Talib  Abdul- Karim PhD.

Abstract:
Background: Rubella is generally asymptomatic in healthy adult, but during the first trimester of pregnancy often leads to fetal death or severe congenital defect, so it is considered as an important public health problem.

Objective: This study was conducted to determine rubella antibody levels among group of women with normal delivery with their newborn babies and another group of mothers with cesarean section and their newborn babies, and its relation to various epidemiological, medical and obstetric problems.

Method: Serum specimens of 166 women with vaginal deliveries and 32 women with cesarean section and their babies were screened for rubella antibody levels by Mico ELISA method.

Result: Rubella antibody levels were < 1.00 (optical density) in 54.2% of women with vaginal delivery (group one) and 71.9% of women in group two (women with cesarean section). Age (significant for group two), mother education, and crowding index were negatively correlated with antibody levels in both groups. German measles vaccination had negative correlation with rubella antibody titers in both groups (significant for group one), while weight of newborn babies was significantly correlated with rubella antibody titer among babies in-group two.

Conclusion: Weakly positive antibodies were found to be higher among women and their babies following cesarean section than the group of women with normal deliveries and their babies, negative correlation were found between antibody levels and age of mothers, educational level, crowding index.

Keywords: Rubella antibody levels and mothers at delivery.

IRAQI J MED SCI ,2007;VOL.5(3):90-96

Introduction:
Rubella infection is generally an asymptomatic childhood disease but during the first trimester of pregnancy often leads to fetal death or severe congenital defect (congenital rubella syndrome, CRS) (1). While the inclusion of rubella vaccination into routine childhood immunization will decrease rubella virus circulating among young children, it will not have immediate impact on the transmission of rubella among adults or the occurrence of CRS (2).

Worldwide, it is estimated that there are more than 100,000 infants born with congenital rubella syndrome (CRS) each year. In 1998, standard case definition for surveillance of CRS and rubella were developed by the World Health Organization (WHO) (3). If applied appropriately, vaccination against rubella protects the susceptible person in 95% of the cases (4). Nearly 50% of CRS can be prevented via vaccination of the sensitive women, based on the recommendations of Advisory Committee on Immunization Practices (ACIP) (5). Enzyme Linked Immune Sorbent Assay (ELISA) is the most commonly preferred test against rubella antibodies in immunized subject (6).
rubella antibodies….. Enas Talib Abdul- Karim

In Iraq rubella vaccination had been adapted in the MMR vaccine and also for schoolgirls, but there is no vaccination program for adult women or serological testing for rubella antibodies for pregnant women. Since 2003 many programs (vaccination programs is one of them), which were running regularly in our country, were affected by the current situation leading to missing of opportunities for having proper vaccination. Also antibodies following vaginal delivery suppose to be higher than those following cesarean section because of uterine contraction that lead to higher level of antibodies delivered to the baby during vaginal delivery. For these reasons and because of the bad consequence of this disease on the reproductive health of women this study was done to determine rubella antibody levels among group of women with normal deliveries and their newborn babies and another group with cesarean section and their newborn babies, and its relation to various epidemiological, medical and obstetric problems.

Materials and subject:

The study sample was divided into two groups, group one includes 166 mothers with normal vaginal deliveries and their newborn babies, group two include 32 mothers delivered by cesarean section and their babies. Data on the demographic, socioeconomic characters of the family, medical & obstetric history of the mother during pregnancy was obtained through well-structured questionnaire form. Both groups were taken from the Al-Kadhimiya Teaching hospital during the period from December 2004- July 2005. Blood obtain from both mothers and babies to measure rubella specific IgG antibody levels via micro ELISA technique. Standardization procedures were carried out for the antigen (Rubella Ag from Virion), conjugate (Antihuman IgG Fab specific, peroxides conjugate, Sigma), and antisera, the optical dilutions were found to be 1/10, 1/500, 1/2 respectively, ELISA test was used following the WHO standard method (7) using the above antigen in proper concentration for coating micro wells as a solid phase.

The test was carried out on the above samples in the Medical College\'s Al-Nahrain University under the supervision of the microbiology department.

Sample values that lie below the cut-off value (mean negative +2SD) were considered negative, and those that were equal to or greater than cut-off value were considered positive. Because we did not have the reference standard to express the results in International units, the antibody levels to rubella (absolute optical density values) were divided into the following groups (10).

- Less than 1.00 = weak positive
- 1.00 -1.99 = positive
- Over 2.00 = strong positive

Analysis of data was done using SPSS statistical program version 11.0 to obtain frequencies, percentages, t-test and correlation test were done as test of significant, P value of ≤ 0.05 was considered significant.

Result:
Rubella antibody levels were < 1.00 (optical density) in 54.2% of women with vaginal delivery (group one) and 71.9% of women in-group two (women with cesarean section), while it was the reverse for antibody titer of > 1.00 table (1). There were no significant differences between the mean rubella antibodies in-group one and two (P > 0.05) and again between babies in the two groups table (2). Majority of mothers in both groups were in the age group 20-29.9 years (58.4%, 50.0% respectively), also higher percentage of mothers in both groups were with education < 6 years (58.4%, 62.5% respectively), women in the second
group had higher crowding index in the 3-5, > 5 than those with normal deliveries (37/5%, 15.6% compare to 24.1% and 8.4%), history of germen measles vaccination, and urinary tract infection during pregnancy were higher in group two than group one (46.9%, 21.9% compare to 30.1, 10.8%), premature deliveries represent 9.0% in the study sample, all of them were in group one, and only one baby had birth weight < 2.5 kg among the second group compare to 10.8% in the first group table (3A&B).

Age (significant for group two), mother education, and crowding index were negatively correlated with antibody levels in both groups, germen measles vaccination had negative correlation with rubella antibody titers in both groups (significant for group one), while weight of newborn babies was significantly correlated with rubella antibody titer among babies in group two (table 4).

Discussion:
Rubella is generally asymptomatic in healthy adults but leads to congenital rubella syndrome in fetus, so it is considered as an important public health problem (8). In this study 54.2% of mothers, 52.4% of babies in the first group and 71.9% of mothers, 68.8% of babies in the
second group had weak rubella IgG antibodies, this result is higher than the result found by Turgut et al (2) 2004 in Turkey (17.2% were seronegative for rubella antibodies). In 1995-96, WHO conducted a review of rubella immunization strategies. Worldwide, 78 countries (more than one-third) reported a national policy of using rubella vaccine. This was closely related to each country’s economic status. Based on the United Nations country classification, rubella vaccine is used in 92% of industrialized countries, 36% of those with economics –in- transition, and 28% of developing countries (9), in 2002 only 124 (58%) of 214 countries or territories around the world had implemented a rubella vaccination program (10). An Australian study found that women born in Asia, sub-Saharan Africa and South America were 5 times as likely as other women to be seronegative for rubella virus (11). Results of the present study are very striking one and might indicate improper vaccination, other point is that rubella antibodies decline over time and may increase the risk of reinfection (12). In a study involving Korean children 18.8% of those who had been vaccinated and 13.8% of those with natural immunity were found to be seronegative for rubella virus after 3 years, an Italian study shows that wild-type rubella virus reinfected 9.8% of vaccinated girls within 5 years (11). Obstetricians should always check rubella serologies in women of reproductive age if they have been vaccinated, rubella serology should also be checked in all pregnancies even if the patients were seropositive during their prior pregnancies (13). Both mother educational level and crowding index were negatively correlated with antibody levels (except for babies of mothers with normal delivery in association with mother education). This is an expected result since crowded environment and low educational level may be risk factors for diseases such as rubella because of easy transmission and inaccurate knowledge about the disease transmission and its impact on health problems. The test used in this study was implemented as a screening test to detect past exposure and no further action was taken for women who had weak or negative antiarubella antibodies.

Conclusion and recommendation: Weakly positive antibodies were found to be higher among women and their babies following cesarean section than the group of women with normal delivery and their babies, negative correlation were found between antibody levels and age of mothers, educational level, crowding index. Because rubella antibodies wane over time, screening for rubella susceptibility is recommended at the first prenatal visit for all pregnant women, standing orders for rubella vaccination after delivery and reinforcement of rubella vaccination program may increase immunization status among women in reproductive age

A RELAPSED ACUTE PROMYELOCYTIC LEUKEMIA TREATED WITH ARSENIC TRIOXIDE ALONE: CASE REPORT

Nabeel S. Murad FRCP, Waseem F. Al Tememi FICMS

Abstract
Acute promyelocytic leukemia is now the most curable subtype of acute myeloid leukemia in adult. It is characterized by 3 main features which are the presence of abnormal promyelocyte in bone marrow, the occurrence of disseminated intravascular coagulopathy and the presence of classical chromosomal translocation t(15;17)(q22;q21) or its variant.

The incorporation of ATRA in the induction over the past 25 years represents one of the most important advances in treatment of AML by inducing more differentiation of leukemic cells into mature granulocytes giving higher complete remission rate and resolution of the life threatening coagulopathy as well as decreases the relapse rate in comparison with chemotherapy alone.

In 1990’s, investigators from China reported that arsenic trioxide (ATO) induces complete remission (CR) in patients with relapsed or refractory APL in 90% of cases by inducing partial differentiation & apoptosis of leukemic cells.

In Al-Kadhimiya Teaching Hospital, we faced such a case of APL who relapsed for second time within 1 year duration of a previously achieved remission, and fortunately we treat the patient with ATO alone that induced CR within 1.5 month duration of treatment then followed by consolidation courses and maintenance treatment to strengthen this remission state that is still existing.

Keywords: myeloid leukemia, acute promyelocytic leukemia, M3 subtype, relapse, all-transretinoic acid, and arsenic trioxide.

IRAQI J MED SCI, 2006; VOL. 5 (2):97-101

Introduction
Thirty-one years old female patient who is a married housewife diagnosed as a case of acute promyelocytic leukemia in June 2001 on the base of clinical picture and hematological investigations.

She received classical induction chemotherapy regimen (7 and 3 regimen), which included Ara-c 100 mg/m²/day (180 mg/day i.v. infusion in 500 ml DW 5% over16-18 hours) and anthracyclin (doxorubicin) in a dose of 45 mg/m² (80 mg/day) i.v. infusion in DW 5% in one hour) together with ATRA (all trans retionic acid) capsules in 45 mg/m² dose (60 mg/day). The latter was continued for the subsequent 2 m.o. She passed in first remission and received consolidation chemotherapy with ara-c & doxorubicine.

On July 2002, she returned back with early relapse of her disease, a new course of chemotherapy plus ATRA decided to be given similar to first course, but the results was partial remission that necessitated re-induction chemotherapy using 2 cycles of mitoxantran 20 mg/day i.v. infusion in day 1 and Etoposide 100 mg/day i.v. for 3 days.

Remission achieved but on August 2003, the patient re-presented with full blown picture of relapsed disease and considered to be 2nd relapse where decision taken to start supportive treatment as well as using, for the first time in Iraq, a new agent therapy for relapsed cases of APL which is [Trisenox ®], arsenic trioxide Jalone without the use of chemotherapy (according to literatures) in a dose of 0.15 mg/Kg/day (12 mg/day) as i.v. infusion for 3 hours continuing daily until achievement of new remission which occurred at 44th dose of treatment where all hematological parameters were corrected (table 1), hand by hand with careful and close observation for the anticipated adverse effects of this agent.
by repeating electrolytes study, coagulation screen, CBC and ECG monitoring.

One month later she received consolidation course of (Trisenox ®) for 3 weeks only in the same dose 12 mg/day by infusion over 3 hours for 5 doses/week, to be followed by intensification chemotherapy and then subsequently by maintenance chemotherapy since that time which includes the following drugs:

1. ATRA every 3 m.o. for 15 days in dose of 45 mg/m²
2. 6 MP 100 mg/ day
3. MTX 25 mg/ week

She is doing fine till the time of reporting the case on the 5th of October 2005.

Historical Background

Leif Hillestad[11], the Swedish author, was the first who give the name of acute promyelocytic leukemia (APL), he concluded in 1957 that APL seems to be the most malignant form of acute leukemia. In 1976, the FAB groups assign this disease as M3 subtype of AML.

Also in 1976, a consistent chromosomal change, the balanced reciprocal translocation between the chromosomes 15&17 [t (15; 17)(q22;q21)] was reported by Rowley et al [2]. So far, APL has been shown to be characterized by 3 features: 1. Presence of abnormal accumulation of promyelocytes in the bone marrow. 2. The occurrence of afibrinogenemia and DIC that is reversed by chemotherapy, and 3. Presence of the classical chromosomal translocation or its variant.

The past 3 decades has shown great advances in evolving therapeutic approaches for APL. In the 70s, the APL was treated by chemotherapy & was considered the most devastating subtype of AML. The
introduction of all transretinoic acid (ATRA) and arsenic trioxide (ATO) by Chinese hematologist since mid 1980s opened a new page in the history of leukemia therapy. ATR A is a derivative of vitamin A; which has improved the complete remission (CR) rate and long-term survival of APL patients \(^3\). On the other hand, the application of ATO further improved the clinical outcome of refractory or relapsed APL \(^{4,5}\).

Lately, a higher quality remission and survival in newly diagnosed APL were achieved when ATRA was combined with ATO as compared to either monotherapy making APL a curable disease \(^6\). So the history of APL could be subdivided into 4 periods: pre ATRA period, incorporating ATRA, integrating ATO, and synergising targeting period.

Since 1996, a large number of reports have shown that ATO induces a CR in 85% to 90% of patients with both newly diagnosed and relapsed APL \(^{7,11,12}\).

Furthermore, after CR is achieved by ATO, molecular remission (i.e. negative for PML- RAR\(\alpha\) transcript detected by RT-PCR) is obtainable either with ATO or with ATRA and chemotherapy as a consolidation treatment\(^9\). It seems likely that ATO used in the post remission therapy could prevent recurrence and achieve a longer survival time\(^{8,9}\).

Mechanism underlying ATO triggered APL cell apoptosis, have been broadly studied. The apoptosis inducing effect is associated with down regulation of Bcl-2\(^{10}\) which correlates with PML- RAR to block neutrophil differentiation\(^{11}\).

**Role of Arsenic trioxide (As\(_2\)O\(_3\)):**

Investigators from China reported that arsenic trioxide induces CR in patients with relapsed and refractory APL in 90% of cases\(^{4,5,8}\) (Table 2). Although the mechanisms have not been completely described, preclinical studies suggested that As\(_2\)O\(_3\) induces partial differentiation and apoptosis of leukemic cells.

Soignet et al., initiated a pilot study of 12 patients with relapsed APL who were treated with Trisenox\(^\oplus\) (As\(_2\)O\(_3\)) at doses ranging from 0.06 to 0.2 mg/Kg/day until leukemic cells were eliminated from the bone marrow as determined by light microscopy (Table 3). 11 patients obtained CR with 8 of the 11 patients who initially tested positive for PML/RAR\(\alpha\) fusion transcript later becoming negative (Table 4) \(^{8,9}\). A multicenter trial of 40 patients confirmed the high CR (85%) (9)(Table 3), furthermore, approximately 78% of patients had no evidence of leukemic clone by PCR after 2 courses of Arsenic trioxide (Table 4)\(^{8,9}\).

The most important toxicities include prolongation of the QTc interval and APL differentiation syndrome. However, two recent reports of sudden cardiac death with (Trisenox \(^\oplus\)) indicate that careful monitoring is warranted.

Currently, Arsenic trioxide is considered to treatment of choice for
patients with relapsed disease, particularly in patient exposed to ATRA within the prior 12 months.

Moyamoya Syndrome
Samir hassan abood FRCS, Abdulameer Jasim Mohamad FICMS

Abstract: Moyamoya syndrome is a chronic progressive occlusive cerebrovascular disorder. We present a 41 years old man who had this syndrome, and presented as intraventricular hemorrhage complicated by communicating hydrocephalus. We describe in this report the clinical features and the diagnostic radiological investigations. The patient was treated by ventriculoperitoneal shunt with full recovery.

Keywords: Moyamoya, Intracranial hemorrhage, Hydrocephalus

IRAQI J MED SCI, 2007; VOL.5 (3) 102-107

BACKGROUND:
Moyamoya syndrome is a chronic progressive occlusive cerebrovascular disorder that was first described by Suzuki and Takaku. The disease is characterized pathologically by progressive stenosis of the distal internal carotid and basilar arteries and their branches, with concomitant enlargement of perforating collateral arteries at the base of the brain to form the so-called Moyamoya vessels. The disease can be unilateral or bilateral. The name Moyamoya coined by Suzuki and Takaku which describes something hazy, like the puff of cigarette smoke drifting in the air, and refers to the angiographic appearance of the network of collateral vessels at the base of the brain. (1,2) This disease was described initially in Japan but is now recognized worldwide with case reports from Malaysia, Turkey and USA. (3,4) (FIG 1)

FIG 1,
Shows the characteristic angiographic appearance.

Case reports of occlusion and narrowing of both internal carotids with network of neovasularity at the base of the brain were published since the 1950s. Kudo in 1968 first introduced the disease in English literature; Nishimoto and takeuchi described an extensive review of 96 cases in the same year. Later in the disease the posterior circulation is involved (5,6,7) with enlargement of extracranial transdural collaterals, including meningeal branches (6). Eventually there is complete obliteration of the internal carotid artery and the cerebral circulation will depend on the external carotid
Moyamoya Syndrome... Samirabood et al

The disease might get arrested at any stage or occasionally shows some spontaneous improvement. The exact etiology of the disorder is not known. There is a familial occurrence in Japan of 7%, and the disease has been seen in identical twins. There is also a significant association between moyamoya syndrome and certain human lymphocyte antigen phenotype (8) as well as certain hereditary diseases such as Down syndrome, neurofibromatosis, and sickle cell anemia (9,10). Moyamoya syndrome is also seen following infectious diseases of the central nervous system, including tuberculosis, meningitis, and leptospirosis. It was also noticed following therapeutic irradiation of the head (especially for sellar and suprasellar lesions), in Fanconi's anemia, connective tissue disorders, renal artery stenosis with hypertension (10), and in patients with type I glycogenesis, craniopharyngiomas, and optic gliomas (10,11).

Moyamoya disease affects children and adults, with peak incidence in the 1st and 4th decades of life. In children the most common symptoms are hemiparesis, speech and sensory disturbances, seizures and transient ischemic attacks (TIA). In adults it usually presents as subarachnoid or intraventricular hemorrhage and acute hydrocephalus. (1,12,13,14) Symptomatology can be intermittent, with light neurological symptoms, or the disease can be progressive with eventual physical and mental deterioration. (9)

The electroencephalogram (EEG) shows characteristic changes. However, the EEG results do not aid in the diagnosis or in predicting the natural history of the patient's disease process. Although other tests have been proposed to evaluate these children, such as radioisotope scanning and cerebral blood flow studies, including single photon emission computed tomography (SPECT), positron emission tomography (PET) and MRI perfusion studies, cerebral angiography remains the definitive diagnostic test (20). It is important that the arteriographer study all circulations, including the external carotid artery system, in order to determine the presence and location of preexisting collateral flow and to determine if surgical therapy feasible. The surgical treatment consists of treatment of hydrocephalus, and revascularization of the brain. The most commonly used procedures are superficial temporal-middle cerebral arterial anastamosis and encephaloduroarteriosynangiosis, which consist of covering the brain with large temporalis muscle flap. However surgical treatment, though improve symptoms due to ischemia, it does not significantly reduce the incidence of stroke.

Key Word: Moyamoya, Intraventricular hemorrhage, Ventriculoperitoneal shunt.

Case report:

We present a 41 years old man who presented with sudden sever frontal headache 40 days before admission, associated with altered level of consciousness, slurred speech and incontinence of urine. By the time he was referred to the Neurosurgical department, the patient had improved, but he still had headache. On examination the patient was conscious, with neck stiffness, and bilateral Papilledema. The rest of his neurological examination was normal, and there was no evidence of neurofibromatosis or any other systemic disease. CT scan, done at the time of the episode shows intraventricular hemorrhage (FIG 2) A four vessel angiogram was obtained which shows typical findings of terminal Lt. internal carotid artery stenosis, and a tuft of moyamoya vessels in the basal ganglion (FIG 3).

A new CT scan was done 2 weak later shows resolution of the heamorrhage but there
was marked dilatation of the ventricles of the brain, with periventricular edema, reported as communicating hydrocephalus. (FIG4). A ventriculo-peritoneal shunt was inserted, the headache was relieved, the Papilledema resolved, and the patient was discharged with no deficit.

**FIG 2.**
Axial brain CT showing extensive intraventricular hemorrhage

**FIG 3.**
Digital subtraction angiography showing Stenosis of the terminal Int. carotid And Moyamoya vessels

**FIG. 4**
Axial CT showing advanced hydrocephalus

**Discussion**
Suzuki and Takaku first used this name in 1969 using Japanese name MOYAMOYA to describe the hazy, puff-of-smoke appearance of the neovascularization, which develops, and since then it has been widely known as moyamoya. Histopathologic examination of the diseased vessels reveals intimal hyperplasia and disordered or redundant internal elastic lamina. There is no evidence of inflammatory vasculitis. The moyamoya vessels themselves can either be normal or show attenuation of the elastic lamina, fibrin deposition with resultant thrombi, and microaneurysm formation. There is usually a striking absence of inflammatory cells in the walls of vessels. Moyamoya syndrome has demonstrated a probable increase in the amount of basic fibroblast growth factor.
in these tissues. This has been suggested to play a role in the development of the arterial wall changes in these patients. Moreover, the response of smooth muscle cells in the vessels of patients with moyamoya syndrome to platelet-derived growth factor, a mitogen of smooth muscle cells, also has been noted to be altered. These changes in the arterial wall lead to intracranial bleeding in adults, while children suffer from recurrent episodes of cerebral ischemia, seizures and stroke \(^{1,12,13,14}\).

The angiographic progression of moyamoya syndrome has been well described in the literature. Matsushima and Inaba correlated the angiographic staging proposed by Suzuki with clinical presentations and noted that symptoms occur when there is an imbalance between the spontaneously developing collateral’s from the moyamoya vasculature, skull base, dura, and leptomeninges, and the degree of brain ischemia caused by the proximal occlusive disease process. The rate of progression is difficult to predict, but it is generally thought that the syndrome has a progressive phase during which the occlusions occur and the collateral’s develop, and a stable phase when all collateral’s are fully developed, the occlusive process is completed, and ischemia attacks disappear \(^{11}\). Clinical disease progression is unpredictable, with slowly developing neurological deficits.

Medical therapy (e.g., corticosteroids, vasodilators, low molecular weight dextran, antiplatelet agents, and anticoagulants) have been tried, but it efficacy remains questionable\(^{1}\). The stenoses continue to progress, usually at an unpredictable rate in a given patient, and medications do not seem to affect this process; however, antiplatelet agents such as aspirin appear to be important in reducing the incidence of symptoms in many of these children, probably because of the many small thromboses and subsequent embolizations that must be occurring distal to the moyamoya stenoses. The authors have noted that in several patients, both pre- and postoperatively, transient ischemic attacks were affected favorably by aspirin intake, and its use is advocated strongly in the treatment of this syndrome. Calcium-channel blockers also have affected the patients' symptoms favorably in several of the authors' cases.

Surgical procedures to treat moyamoya syndrome, with the exception of attempts to denervate the cerebral vasculature proposed by Suzuki and colleagues, have been designed to augment transdural collaterals that are already part of the ongoing moyamoya process. Cervical perivascular ganglionectomy, which involves resection of the stellate ganglion and sympathetic nerves around the carotid arteries, results in only temporary improvement of symptoms by increasing collateral circulation. However, it does not halt the progression of the disease.

Yasargil performed the first superficial temporal artery (STA) to middle cerebral artery (MCA) bypass in a child with moyamoya syndrome. This can very effectively increase hemispheric collateral flow. However, this procedure may be technically difficult in children \(^{21}\). Other operative techniques have depended upon the natural tendency of the ischemic brain to form collateral flow from any available source. Encephalomyosynangiosis involves the placement of the inner surface of the temporalis muscle directly on the brain surface following an extensive temporal craniotomy. Recent reports from Japan have documented improved clinical status and dramatic postoperative angiographic results in 70 to 80\% of cases \(^{13}\). Complications related to the procedure include transient focal seizures probably secondary to the intrinsic muscle activity of the temporalis and the development of chronic subdural hematomas. Alteration in skull configuration following the relocation of the temporalis muscle also may be disfiguring. The large skin incision and dural flap required for the procedure have the potential to interrupt a number of preexisting collaterals to the brain from the dura, and the authors have felt that this procedure has limited application in the treatment of children with moyamoya syndrome.

Other techniques have been used to provide collateral flow in the appropriate patient. Neovascularization was noted initially in a patient in whom the bone flap was not replaced following a STA-MCA bypass. Spetzler and colleagues noted multiple transdural collaterals occurring 6 weeks after an intact STA was sutured to the arachnoid in a patient with no satisfactory recipient vessel at
the time of the intended STA-MCA anastomosis. Matsushima and colleagues transposed the intact STA with a strip of attached galea to a narrow dural opening beneath a linear craniotomy in hope of promoting transdural collateral formation, naming their procedure encephalo-duro-arterio-
asangiosis. Subsequent papers by Matsushima and coworkers have demonstrated dramatic enlargement of the donor vessel, increased transdural collateral formation, and impressive changes such as a decrease in moyamoya vessels and increased MCA filling. Clinical and EEG improvement also was noted, although intellectual function appeared unchanged. Matsushima and colleagues recently have suggested that STA-MCA anastomosis combined with Encephalomyosynangiosis may be superior to encephalo-duro-arterio-
asangiosis in development of collateral circulation and operative clinical improvement. However, the technical aspects of in anastomoses of small vessels in children remain challenging (2,21,22,23,24,25).

The patient in this study was an adult, and probably passed the active disease stage. The problem in this case was mainly that of hemorrhage and raised intracranial pressure. In such cases ventricular drainage is advised. (1)

The treatment was directed at relieving hydrocephalus. We used ventriculoperitoneal shunt (VP). The shunt is important in this case because it not only relieves high pressure but it will also improve the cerebral blood flow (CBF) which is an aim in all surgical procedures. Reducing intracranial pressure will improve cerebral perfusion pressure, according to the equation that cerebral perfusion pressure=mean arterial blood pressure minus intracranial pressure (ICP).

خليفة الدراسة: الأورام اللمفاوية هي مجموعة غير منتجية من أورام خلايا باء أو تاء والتي عادة تنشأ في العقد اللمفاوية. وهي تضم إلى أورام هويدجك و اللاهوهجك اللمفاوية. إن تميز الالوان الفيسيولوجي ما بين أكثر الخلايا و موتها هو صفقة لكل الأورام الخبيثة. لقد كان هناك اهتمام متزايد بدور موت الخلايا الموجود في تكوين الورم اللمفاوي. بناءً على الأساس الجزيئي إن موت للخلايا الموجود هو بسبب تنشيط إنزيم الكاسبيز من خلال الطرق الخارجية والداخلية. الطريق الخارجي يركز على عائلة عامل تنخر الورم، والتي يرتبط فيها الرايب إلى مستقبل سطح الخلية. وهذا بدوره سوف يحدث موت الخلايا الموجود. إن مستقبل فاس هو أحد أعضاء العائلة يرتبط عامل تنخر الورم عامل يعاني الدم. عائلة فاس تتكون من مستقبل والرابطة والشكل الذائب. فاس الذائب سوف يتنافس مع مستقبل فاس للاربطة مع الرايب، وبذلك سوف يتفاعل مع موت الخلايا الموجود الذي يتوافق فاس الرايب.

هدف الدراسة: قياس مستوى فاس الذائب في مصل دم مرضى أورام اللاهوهجك اللمفاوية. بالإضافة إلى تقييم العلاقة بين تركيز فاس الذائب في مصل الدم ومؤشرات سريري محددة، مؤشرات الدم، والعلاج الكيميائي لورم اللاهوهجك.

المرضى والطرق: شملت الدراسة 30 من مرضي 14 مريضا "مصابًا بورم اللاهوهجك بضمنهم 19 ذكرًا و11 أنثى. من هؤلاء المرضى، 14 مريضا."شمخوا حديثا". بالإضافة إلى ذلك 30 شخص سليم استخدموا كمجموعة مرجعية. لقد قبلت المرضى وأخذ منهم تاريخهم المرضي وقصصهم سريريا. وسجيت منهم ومن العينة الضبطية عينة تم تدقيق تركيز فاس الذائب في مصل الدم واستخدام عدة شبكات الأثر من شركة كيمكوب. وكذلك 30 من المرضى الذين مصابون في مصل الدم ومصبوس السليمين المصفحات المطلقة وعدد السليمين الم صفيحة الاورام اللاهوهجك بعلاج حالي الدم وتركيز الهيموغلوبيين وعدد السليمين المصفحات المطلقة.

النتائج: هذه الدراسة كشفت أن تركيز فاس الذائب كان مرتفعا بدرجة ذات أهمية إحصائية عند مرضى أورام اللاهوهجك اللمفاوية مقارنة بالمجموعة الضبطية (0.001). هذه الزيادة كانت أعلى جزيئيًا، ذات أهمية إحصائية عند المرضى الذين أخذوا العلاج ومتعلقة بصورة وطيدة بالدرجة الجيني. الورم اللاهوهجك اللمفاوي (0.001 و0.05 وعلى التوالي).

الاستنتاج: إن فاس الذائب هو فحص سبيط، غير إعتيادي وموجود للوقت. ومن الممكن أن يستعمل كمؤشر مختبري مفيد سريريا عند مرضى أورام اللاهوهجك اللمفاوية. إن فاس الذائب يمكن استخدام كمؤشر معنوي لتمييز شدة الورم والتكهن بمسير المرض، وكذلك التخطيط لحالة العلاج عند مرضى أورام اللاهوهجك اللمفاوية.

مفتاح الكلمات: فاس، اللاهوهجك.

أهمية الدراسة الشكلية للنواة في سرطان الثدي

زيب عبد الجبارسن العبدي١، فوزية فوزي١، حسن بن عبد الجبارسن العبدي٢

الخلاصة

خلفية الدراسة: يعتبر سرطان الثدي من أهم الأورام الخبيثة لدى الإناث. وهناك دليل على أن استعمال العلاج الكيميائي المساعد في حالات سرطان الثدي الذي يحتاج أحيانًا إلى اختبار دقيق للمرضى، خصوصًا للذين تواجه شفاء إليهم.

ويعتمد اختيار المريض على عوامل كمية عديدة، مثل عمر المريض، حجم الورم، درجة خبث الورم، وعوامل أخرى، وتغطية للقياس الشكلي للنواة وسهولة موضوعية وكمية لتقديم العوامل الكيميائية للورم، حيث أظهر فحص مساحة النواة زيادة واضحة عند قياسها في خلايا الثدي الطبيعية ومقارنتها بالخلايا السرطانية.

وإشاره إن هذه القياسات لها علاقة صعبة مع براءة السرطان خلال سنوات ونصف من تشخيصه.

هدف الدراسة: تقييم بعض العوامل الكمية لسرطان الثدي على طريق القياس الشكلي للدورة بواسطة الحاسب.

المواد وطرق إجراء الدراسة: تم إعادة فحص أربع وخمسون حالة لسرطان الثدي القذبي (مشكلة من قبل أخصائي التسجيل المرضى) والمعروفة حجمه وتصنيفه النسيجي وعمر المريضة أثناء التشخيص. في كل حالة تم فحص 100 مقاطع مجهري وفي كل مقطع تم قياس مساحة 300 نواة باستخدام جهاز التحليل الشكلي تحت كبرٍ 400.4.

النتائج: أظهرت التحريات وجود فروق مميزة إحصائيًا عند قياس مساحة النواة بين درجات التمايز الثلاثة (p<0.01). وكذلك بالنسبة لأورام باليال قطرها 5 سم، حيث ظهرت قيم مساحة النواة أعلى من قيمها في الأورام التي يبلغ قطرها أقل من 5 سم (p<0.01). في حين لم يكن هناك اختلاف إحصائي واضح في مساحة النواة للأورام عند المرضى أكثر من 50 عام أو أقل من 50 عام (p>0.01).

الاستنتاج: إن دراسة التحليل الشكلي للنواة كاستعمال متغير مساحة النواة قد يكون ذات فائدة موضوعية عند تقييم العديد من العوامل الكيميائية لسرطان الثدي.

مفتاح الكلمات: القياس الشكلي للنواة، العوامل الكيميائية، سرطان الثدي.

أسباب حدوث الصرع البؤري في مجموعة من المرضى العراقيين
حسن عزيز الحمداني

الخليصة

خليفة الدراسة: الصرع البؤري هو أكثر الأنواع شيوعًا في المرضى المصابين بمرض الصرع. هذا النوع هو بؤرة متزايدة في منطقة محددة من الدماغ. أضرار معينة أحيانًا أو تركيبية تؤدي إلى زيادة القابلية للإصابة بالمرض. النوبات الصرعية قد تكون نتيجة مرض يصيب الجهاز العصبي أساسًا أو أجزاء أخرى من الجسم غير الجهاز العصبي. الأضرار التركيبية في الدماغ تزداد احتمالية وجودها مع وجود تاريخ مرضي طويل لمرض الصرع عند المصاب بهذا المرض.

هدف الدراسة:
1. اكتشاف أسباب الصرع البؤري
2. توضيح العلاقة بين المرض و عمر المريض

المريضي وطرق الدراسة: دراسة توثيقية ل 106 مريض في مستشفى الكاظمية التعليمي مصابين بمرض الصرع البؤري تتراوح أعمارهم بين 6 إلى 73 سنة، 52 ذكور و 54 أنثى.

التقني: لهذه المجموعة من المرضى 27% منهم الفحص التشريحي كان غير طبيعي. ورم الدماغ وجد عند 19.7% منهم من الأعمار أقل من 40 سنة. بينما وجد احتشاء الدماغ عند 25.5% من المرضى و معظمهم من أعمار أكثر من 40 عام. 83.7% من مرضى الصرع البؤري المعتمد وجدت البويرة السببية في الفص الصدغي و 16.2% في الفص الأمامي. بينما وجد إن نسبة وجود البويرة في الفص الأمامي 89% في مرضى الصرع البؤري البسيط و 75.4% من مرضى الصرع البؤري البسيط و 35.1% من مرضى الصرع البؤري المعتمد تظهر لهم أعراض تركيبية.

الاستنتاج:
1. احتشاء الدماغ هو أكثر الأسباب شيوعًا لمرضى الصرع البؤري من الأعمار أكثر من 40 سنة بينما ورم الدماغ هو أكثر الأسباب في الأعمار أقل من 40 سنة.
2. الصرع البؤري مراعل للأضرار التركيبية في الدماغ
3. التاريخ المرضي الطويل يجعل الارتباط بين المريضي والأضرار التركيبية أقل وضوحا.

مفتاح الكلمات: الصرع

دراسة انتشار الجراثيم لممرض الباراتايفونيد نوع -أ- والأفات الناجمة عنها في الخمج التجريب في الفئران البيضاء
خليل حسن زناد الجبوري

الخلاصة

خلفية الدراسة: تبقى الإصابة بمرض الباراتايفونيد ذات أهمية صحية ولكون الإصابة بهذه البكتريا متخصصة في الإنسان والقرود إلا أنه في الجرع العالية منها يمكن إصابة الفئران البيضاء وعن طريق الخلب.

أهداف الدراسة:
1. دراسة انتشار عصيات الباراتايفونيد نوع -أ- في أعضاء الفئران البيضاء.
2. دراسة الآفات الناجمة عنها في مختلف الأعضاء.

طرق العمل: استخدمت 10 أضعاف الجرعة النصفية القاتلة في الفئران والتي كانت ٢٠٠٨ خلية بكتيرية في المليون الواحد. أعطيت هذه الجرعة عن طريق الخل للفئران والأفات الناجمة عنها في مختلف الأعضاء وفترات معينة وملحقة بعد حقن الجراثيم.

النتائج: استمر انتشار الجراثيم لعصيات الباراتايفونيد نوع -أ- في الطحال والكبد ولمدة ١٧ و١٦ يوم على التوالي بينما استمر انتشار الجراثيم العقد النصفية النافعة والرئتين لمدة ١٩ يوم وفي الكلي ودم الفئران لمدة ٥ أيام. كان أبرز الأفات تجمع العدبات والوذمة في الكبد، الطحال والعقد النفاوية والتي تحل محلها خلايا وحيدة النواة مع تكاثر الأورمات النافعة في الفترة الأخيرة للمرض.

الاستنتاج: عصيات الباراتايفونيد نوع -أ- ذات أعراضية واطئة في الفئران البيضاء من خلال توزيعها في أعضاء الفئران البيضاء والأفات الناجمة عنها.

مفتاح الكلمات: الإصابة بعصيات الباراتايفونيد نوع -أ- في الفئران.
اكتشاف حاملات مرض دوشن العضلي بفحص فعالية أنزيم CPK مع تخطيط العضلات التقليدي

عبد المطلب عبد الكريم الشيخلي، سلام فؤاد محمد ربيع، حسن عزيز الحمداني

الخلاصة

خلفية الدراسة: أن مرض دوشن العضلي هو مرض مغم وذو وراثة مرتبطة بالكرموسم x الأنثوي، ويتمدشع عضلي في العضلات الهيكلية القريبة بصورة متزايدة بدأ من الطفولة المبكرة مروراً في مرحلة الراحة حيث يكون المريض مقعداً والموجة نتيجة العجز التنفسي نهائية العقد الثاني أو الثالث. بالرغم من أن غالبية حالات مرض دوشن أو بيكر العضلي غير ظاهرة عليهم أعراضه، لكن بالإمكان معرفتهم من خلال التغيرات السريرية الطفيفة مثل ضعف العضلي المحدود أو بروز عضلات الناحية. بينما نجد لدى بعضهن ارتفاع معدل فعالية الأنزيم العضلي وتفاقم بعض العضلات في التخطيط العضلي.

هذا الدراسة: من هذه الدراسة هو اختبار قيمة الأنزيم العضلي والتحكيم العضلات CPK التقليدي لأكتشاف حاملات المرض في مجموعة من الأمراض العرقية لمصابين بمرض دوشن وبيكر العضلي.

المريض والطريقة: تمته هذه الدراسة في مستشفى الكاظمية التعليمي/قسم طب الجملة العصبية للقريبة المحدودة بين تشري من الأول 2002 إلى كانون الأول 2003 تم تخلصاء دارمه 20 إمرأة حاملة لمرض دوشن وبيكر العضلي، من خمسة عشر عائلة عائلة دوشن وعائلتان بيكر. وقد تم تدشين النتائج لمجموعة أخرى مكونة من عشرين أمراً تم جمعها عشوياً لكل إمرأة مشتركة في الدراسة تم آخذ التاريخ العرضي والفحص السريري الكامل يضمنا فحص قوة العضلات البدني وتدرسة وتحليل شجرة العائلة، وتم أخذ نماذج من الدم الورديي لفحص معدل الأنزيم العضلي CPK، وتحت سطع القلب فحص القلب بالوجوه الصرعية وتحت بط العضلات الصلدية.

النتائج: وجدت هذه الدراسة احذاء وحيدة فقط (4%) عندما ضعف بسيط في العضلات الهيكلية القريبة. وفيما يخص شمول القلب كانت نسبة ضئيلة جداً مرضية واحدة فقط (2%) عندما توقع بسيط في الطفولة الأصغر للقلب، وأحد عشر امرأة (55%) حاملة وجدت لديها ارتفاع معدل الأنزيم العضلي CPK. وقد لوحظ وجدت علاقة سلبية بين عمر المرأة الحاملة للمرض وعمر الأمزيم العضلي سعة حالات لمرض دوشن العضلي (23.94%) وجدت دلالة تكاملات كاسبية في العضلات الهيكلية القريبة في فحص تخطيط العضلات وكان هذا جلياً في عضلات الأطراف العليا. وهو أيضاً كاسبياً إحساسياً.

الاستنتاج: بما أن الأنم AL CPK وتفصيم العضلات التقليدي هما من الفحوصات البسيطة وقليلة التكلفة ونوعية توقفصة إلى حد ما في نسبة من الحاملات لذا يمكن استخدامهما لكل الحاملات المحتملة في عوازل مرض دوشن وبيكر العضلي كفحص احتمالي بسيط. وعندما لا تظهر أعراض الجدد إلى عمر مبكر وفحص تخطيط العضلات أعمد أكبر ذلك لتطلب CPK قدر من تعاون المريض. وهذا له وقظ مهم على الاستشارة السريرية هادفة لمنع انتشار المرض.
الفتح الكلمات: دوشن وبيكر العضلي، الحاملات، أنزيم cpk، تخطيط العضلات التقليدي.

الترابط بين النحاس و تأكيد البروتينات الدهنية عالية الكثافة والسيطرة الأخرى

بالنسبة إلى فرط الزلال الضئيل في الإدرار عند مرضى السكري ( نوع 2).

محمد لطيف أليااي، حاشم مهدي حاشم، غسان عبد الأمير الشماغ.

الخلاص:

خلية الإدارسة: يرتبط داء السكري بنسب عالية من الوفيات بسبب اعترافات الأوعية الدموية والكلي التي لا تكون للأسباب الأساسية المعروفة، وبالرغم من عدم كفاية الأدلة فإن الجهد أنتكسدي وأنتكسدي، وزائدة النمط ودرجة السيطرة الأخرى، وكذلك زيادة نسبة فوق الأكاسيد الدهون الدم يجعلها من العواجل المسليبية لأمراض الأوعية الدموية أما علاقة النحاس بكل ذلك فما هو معروف عنه قليل نسبيا.

هدف الدراسة: هو قياس دلالات زيادة الجذور الحرة وآكاسيد الدهون مثلة بال-MDA وأكاسيد البروتينات الدهنية وتركيز النحاس ونسبة الدهون في الدم وتركيز الهيموغلوبين المشكر.

وشملت الدراسة 55 مريضاً بداء السكري ( نوع 2 ) ومقارنتها ب représente ( مجموعة السيطرة )

النتائج: أدت إلى تقسيم مجموعة المرضى إلى نوعين:

1- المصابين بفرط الزلال في الأدرار بدرجة قليلة

2- المرضى الذين كانت نسبة الزلال في الإدرار طبيعية

والمقارنة مع نتائج مجموعة السيطرة ظهرت زيادة ملحوظة عند مرضى السكري في تراكيز أكاسيد الدهون مثلة بال- MDA وآكاسيد البروتينات الدهنية على الحالة الكثافة حيث أظهرت في المجموعة الأولى نقصان مع وجود علاقة طردية ملحوظة بين تركيز النحاس وال MDA من المرضى فقط مع الهيموغلوبين المشكر.

وقد تزامنت هذه التغييرات مع صغر حجم البروتينات الدهنية الخفيفة (HbbA1C) عند مرضى السكري

وبدأت الدراسة التفسيرات المحتملة للظواهر المذكورة.

مفتاح الكلمات: النحاس، أكاسيد الدهون، داء السكري، فرط الزلال الضئيل في الإدرار.

دور الالتهابات المتأخرة لإقليم مستشفيات خليا بدم البيض البشري- الصنف الثاني في استجابة الخلايا اللمفية ضد مستضدات الحميات المعوية والعدوية
وتشرح أصداء هذه المستضدات في الأطفال المشتركين في مرض السكر من النوع الأول

إيمان مهدي صالح، نزار عبد الهيميم

الخلاصة

خلفية الدراسة: أثبتت العديد من الدراسات أن للفايروسات دوراً تؤدي في إحداث أمراضية مرض
السكر من النوع الأول وقد يكون لها دوراً في بدء عملية تحظيم خلايا بيتا في البنكرياس.

هدف الدراسة: الهدف من الدراسة هو تقييم المعوية الفيروسية للخلايا اللمفية بعد تطبيقها
بمستضدات السمك المعوية والتي تشمل فايروس الكوكسالي نوع (CVB) B وفايروس شل (Adenovirus) للأطفال، خاصة ً ذات البالغة العربية (CVB) B وفايروس شل (Adenovirus) للأطفال من النوع الأول ومجموعة من الأطفال الأصحاء المصابين بمرض السكري من النوع الأول ووضوعة مع التفاوت في التفاعليات التربيني النسيجي ضد IgG من الصنف الثاني وبعض الكليوبوليتان المناعية نوع (HLA) هذه الفايروسات.

طريقة العمل: شملت الدراسة ستون مريضاً، حيث تم الاختيار من مركز مخصص لمرض السكري من النوع الأول (مشغلي بالإصداع خلال فترة اسبوع من خمسة أشهر) والذين تم اختيارهم من المركز الوطني للسكري / الجامعة المستنصرية للفترة من مارس 2002 ولغاية تشرين الأول 2005. ولفض ضوء المقارنة تم اختيار مجموعة من الأطفال (50) طفلاً الإصحاء ظاهرة لفريبادن الديه عن وجود البالغ أطفال الخلايا لمستضدات التربيني النسيجي – الصنف الثاني، ثم قياس الفعالية الفيروسية للفيروسية الفيروسية في الكليوبوليتان المناعية私たち من الصنف الثاني وضمن القياسات الملاحظة (ELISA) ضد الفايروسات الثلاثة باستخدام طريقة IgG المضافة المعيارية.

النتائج: أظهرت الدراسة الحالية انخفاضاً معيناً في الفيروسية الفيروسية خليا اللمفية كاستجابة
للفايروس CVB والمعوية. وكذا باستطام فايروس CVB و Foxos والمعوية اللمفية (5) وفايروس CVB و Foxos.

الاستنتاج: اكتسب الدراسة ملاحظة عموماً في الأطفال المصابين ولكنها ازدادت في الأطفال IgG الحامل للفيروسات المناعية نوع HLA من الصنف الثاني ووميؤين للكليوبوليتان المناعية نوع IgG المضافة الفيروسات.

ملاحظات الكاملا: مرض السكر من النوع الأول، مستضدات التربيني النسيجي – الصنف الثاني، IgG الفيروسية الفيروسية خليا اللمفية، الكليوبوليتان المناعية نوع IgG B الفيروسية الفيروسية خليا اللمفية، الكليوبوليتان المناعية نوع IgG B نوع المصري 5 وشمل الأطفال والحمي الغدية.

البروتينات الشحمية المؤكدة لدى المرضى المصابين بارتفاع ضغط الدم الأولي على
أعمال علاجية مختلفة

فيصل غازي جاسم، عبد الرحمن الباز، غسان عبد الأمير الشماع.

الخلاصة:

الخلفية: إضافة إلى فرط كولسترول الدم والتدخين، يعتبر ارتفاع ضغط الدم (وهو مرضاً مزمن مرتبطة بالعديد من المضاعفات القلبية الوعائية) واحدًا من عوامل الخطرة الرئيسية لأحتشاء الأوعية الدموية، وآثراً على بعض الدراسات أن بعض الأدوية المضادة أو المهيبة لارتفاع ضغط الدم قد تؤدي إلى حدوث تأثيرات غير مرغوب بها على مستوى الشحم في الجسم وكذلك آثاره العناصر الضلائية.

هدف الدراسة: نبين دور الجهد التاكسيدي وفوق أكاسيد الشحم في ارتفاع ضغط الدم وتأثير مختلف العلاجات الطبية عليها.

الأشخاص وطرق البحث: الدراسة الحالية تتضمن قياس مستوى فوق الأكاسيد الشحم للدم، نقط شحم الدم، وفحص الزلق في الإدار لدى (12) مريضاً مصاباً بارتفاع ضغط الدم تراوحت أعمارهم بين (30-40) سنة، وتم تصنيفهم إلى مجموعات تأثيرة ثلاثة بالاعتماد على نمط العلاج: (التيتيونول والكابتوبريل ونظام سيطرة بدون عقاقير) وتم مقارنة النتائج مع نتائج مجموعة من 45 شخصًا سليماً ظاهريًا (مجموعة السيطرة).

تراوحت مراحل مراقبة المرضى من 3-7 سنوات.

النتائج: أوضحت النتائج أن المرضى المصابين بارتفاع ضغط الدم يعانون من ارتفاع معنوي في مستوى المالون ثنائي الأليافون والنسبة المثلية لأكاسيد البروتين الشحمي غير عالي الكثافة وانخفاض معنوي في نسبة المثلية لأوكسيد البروتين الشحمي عالي الكثافة في مصل المرضى مقارنة بمعيار السيطرة. وعزى هذا الاختلاف في التوزيع الممكن للمؤكدة وسياسات التأكسد إلى ارتفاع ضغط الدم أو إلى الأعراض الجانبية للعقاقير المضادة أو المهيبة لارتفاع الضغط الدم. وارتفاع العقاقير المضادة أو المهيبة لارتفاع ضغط الدم أظهر نتائج مختلفة لمصطلح أكاسيد الشحم، والنتائج الأفضل كانت للمرضى المعالجين بعقار كابتوبريل، وظهور اختلاف معنوي بين مجموعات المرضى يدعم هذه النتيجة.

وأشارت نتائج الدراسة إلى أن فرط شحم الدم لدى مرضى ارتفاع ضغط الدم يتميز بزيادة مستوى الكليبرين الثلاثي و الكوليسترول المصحح زائدة في الدم من مصل المرضى تحت نظام سيطرة علاجية بعقار أنثيروتول.

الاستنتاج: يعاني جميع المرضى ارتفاع ضغط الدم من خطورة الإصابة بتصلب الشرايين وخصوصاً العقاقير دون نظام سيطرة علاجية بعقار، ووفقاً للنسبة الجزئية بين الكليبرين الثلاثي إلى البروتين الشحمي عالي الكثافة، فدين دفائق صغيرة كثيرة للبروتين الشحمي واطي الكثافة في مصل الدم عند هؤلاء المرضى.

وتمت مناقشة الأداب المقدمة المؤدية إلى تلك النتائج.

الكلمات المفتاحية: ارتفاع ضغط الدم، الأكاسيد الفوقية للشحم، البروتين الشحمي عالي الكثافة المؤكدة.

انتشار مرض باركنسون في منطقة الكاظمية (مدينة بغداد): دراسة مجتمعية

عبد المطلب عبد الكريم، أمجد داوود نيازي، عمار فاضل عبد الله

الخلاصة

違って الدراسة: مرض باركرسن: مرض تحطمي مزمن يصيب على الغالب البشر فوق 40 سنة. دراسة انتشار المرض حاسم لتخطيط الصحة العامة خصوصا بعد التقدم في السن عالميا. هناك بعض الاختلافات العالمية في نسب الانتشار المخمنة والأرقام مجهولة في بلادنا.

هدف الدراسة: لتخمين انتشار مرض باركرسن في منطقة الكاظمية.

طرق العمل: دراسة مجتمعية أجريت كمسح عرضي على العينة العشوائية من سكان المنطقة.

النتائج: 25 مريض باركرسن تم التحقق من عينة عشوائية من 22,986 فرد (13%) كانت 32 ذكور، 33 كانت إناث. 6 من المناطق الريفية البعيدة و 19 حضرية. ثلاث حالات (12%) شُخصت حديثاً. الارية كان مريض باركرسن السائدة للبداية (90%). 19 حالة كان عداها تدخل ثاني من المريض، بالرغم من البداية الأحادية الجانب لكل الانتشار العام كان 8.05 لكل 1000 سكان. نسبة الانتشار وضعت زيدة ثابتة بالعمر. نسبة الانتشار حسب الجنس للذكر 14/11/001 سكان وللناثي 3/01/001 سكان. نسبة الانتشار المعتادة إقامة كانت 3.143 و 94.3 لكل 1000 سكان للفتيان العشائري والعشائري على التوالي.

الاستنتاج: نسبة انتشار مرض باركرسن أوطأ من الأرماق في أوروبا وأمريكا الشمالية، لكن أعلى من تلك أفريقيا والصين. يزيد بشكل ثابت بزيادة العمر. لم يكن هناك اختلاف هام للذين أو السكان في الريف في نسبة الانتشار. رقم الانتشار يمكن أن يُعتمد إلى سكان مدينة بغداد بسبب التركيب والخصائص السكانية المماثلة إلى تلك من منطقة الكاظمية.

الكلمات المفتاحية: مرض باركرسن

الفحص السريري مع دوبلر الملولن لتقييم أمراض الثدي الحميدة والخبيثة

حكمت عبد الرسول حامد، بشار عباس

الخلاصة

خلفية الدراسة: يعتمد نمو وانتقال الأورام الخبيثة على توليد الأوعية الدموية (Angiogenesis)، كما ويتسبب التوليد المؤشر لانتشار الورم مبكرًا.

هدف الدراسة: استخدام إشارات دوبلر الملولن لدراسة وتقييم جريان الدم في أورام الثدي وتمييز الحميدة منها عن الخبيثة.

طريقة العمل: دراسة مستقبلية شاملة 83 مريضة، أجري الفحص السريري الدقيق مع فحص دوبلر الملولن بواسطة جهاز الأمواج فوق الصوتية للثدي وأخذ بنظر الاعتبار مايلي: وجود أو عدم وجود إشارات دوبلر الملولن مع حساب عدد الأوعية الدموية، التوزيع الشكلي للأوعية الدموية وقياس أقصى سرعة لجريان الدم حول وداخل أورام الثدي.

النتائج: بالاعتماد على الفحص السريري تم تشخيص 23 حالة مرضية خبيثة و56 حالة مرضية حميدة في الثدي وكانت الحساسية (91.5%) أما النوعية فكانت (80.8%). ووجدت إشارات دوبلر الملولن في جميع الأورام الخبيثة (100%) و(79%) منها في الأورام الحميدة، بالإضافة إلى أن عدد الأوعية الدموية في الأورام الخبيثة أكثر مما هي في الأورام الحميدة حيث كانت الحساسية لأكثر من 3 أوعية دموية (85.7%) أما النوعية (91.9%). وجد أن شكل الأوعية الدموية في الأورام الخبيثة هي نافية وسطية بينما هي محيطية في الأورام الحميدة وكانت الحساسية (90%) و(89%) أما النوعية (91.8%) و(91.9%) لسعة جريان أكبر من 15 سم/ثانية.

وجمع نتائج فحص دوبلر كانت حساسية التشخيص (90.4%) أما النوعية فكانت (96.7%).

المراجع:

نقل نسيج مبيضية: طريقة وموقع جديد لتحقيق نمو الجراثيم المبيضية في الفئران

كموديل لأدنى الإنسان

محمدأق محمدزاد فخرالدين 1، فؤاد كاظم الربيعي 2، ابتسام جاسم سوداني 3

الخلاصة

Khالفة الدراسة: تم استخدام نسيج مبيضي (Ovarian tissue transplantation) لتعزيز نمو الجراثيم في الفئران. الهدف من الدراسة: تشكيك نمو الجراثيم في الفئران بطرق جديدة (Gonadotropins).

طرق العمل: تم تخدير ثمان واربعين أنثى فأر وفتح تجويفها البطني، ثم نقل قطعة صغيرة من نسيج ال.gender في الجانب المقابل وعدهما إغلاق التجويف البطني. تم تقسيم أنثى الفئران لحافة إلى ثلاثة مجامع اعتمادًا على وقت حكم نشوبات القد، مما حفز بالحلول الفسيولوجي المعقم، أما المجموعة الثانية (G-2) فقد أظهرت مئات الفئران أربع درجة أفرع متأنية بعد العملية الجراحية مباشرة. في حين حفظت المجموعة الثالثة (G-3) بنشبات القد لأربعة أيام متأنية بعد العملية الجراحية ثمانيات أيام. تم نقل نسيج مبيضية ونوعية البوياضات والتفخيرات النسيجية للأنسجة المبيضية المنقلة.

الناتج: أظهرت نتائج مجاميع التجربة الثلاثة عدم فقدان قطع الأسماك المبيضية المنقلة وعدم ظهور تأثيرات جانبية ضارة على الإناث. تم تحقيق أفضل نمو للجربين المبيضية لدى إناث المجموعتين الأولى والثانية. تم الحصول على أفضل جراثيم مبيضية ناضجة من القطع النسيجية المنقلة لإناث المجموعة الثانية ودرجة أقل لإناث المجموعة الأولى. ظهرت أفرع درجة نمو للجراثيم المبيضية من القطع النسيجية للمباضا لناتج المجموعة الثالثة بالمقارنة مع المجموعتين الأولى والثانية. تم الحصول على بوياضات غير ناضجة وناضجة محاطة بالرکام المبيضي من التحليل الجربين النامي للأنسجة المبيضية المنقلة.

الاستنتاج: تؤكد نتائج الدراسة الحالية إمكانية نقل أسماك مبيضية إلى تحت غشاء الكلية وحصول نمو للجراثيم المبيضية. كذلك تُهدي فسحة الجسم نحو وتطوير الجراثيم المبيضية في موقع آخر غير موقع المبيض الطبيعي. فهذا حافة لإجراء دراسات أضافية على إنجاز وإخلاص البوياضات خارج الجسم وعمليات نقل الأجنحة.

مفاتيح الكلمات: الفئران - المباض - نقل وزراعة الأنسجة - نمو الجربين المبيضية - منشطات القد.

دراسة الأجسام المضادة للروبيلا عند الأمهات وأطفالهن بعد الولادة الطبيعية مقارنة مع الأمهات وأطفالهن بعد أجراء العملية القيسارية

إيمان طالب عبد الكريم

الخلاصة

خلفية الدراسة: تعتبر الروبيلا (الحصبة الألمانية) من الأمراض التي لا تسبب أعراض مرضية عند البالغين، ولكن إصابة الحوامل بالمرض في الجزء الأول من الحمل قد يؤدي إلى وفاة الجنين أو أحداث تشوهات خلقية عنده، لهذا تعتبر الحصبة الألمانية من الأمراض التي لها أهمية لصحة المجتمع.

هدف الدراسة: أجري هذا البحث لتحديد مستوى الأجسام المضادة للروبيلا عند الأمهات بعد الولادة الطبيعية وأطفالهن ومجموعة ثانية من الأمهات بعد أجراء العملية القيسارية لهن مع أطفالهن ومدى علاقتها مع مختلف المشاكل الووثانية والطبية.

طريقة العمل: تم أخذ نموذج دم من 162 امرأة بعد الولادة الطبيعية وأطفالهن (المجموعة الأولى) وكذلك من 37 امرأة بعد أجراء عملية قيسارية لهن مع أطفالهن (المجموعة الثانية) ثم أجري فحص الأليزر على نماذج الدم لمعرفة مستوى المضادات للروبيلا عندهن.

النتائج: كان مستوى الأجسام المضادة للروبيلا أقل من واحد عند 32% من النساء في المجموعة الأولى و 71.9% من النساء في المجموعة الثانية، كان مستوى الأجسام المضادة للروبيلا ذو علاقة سلبية مع العمر عند الأمهات ( ذو مغزى إحصائي عند المجموعة الثانية) وكذلك مستوى التعليم عند الأمهات ومؤشر الكثافة السكانية. وأظهرت النتائج أن أخذ اللقاح ضد الحصبة الألمانية له علاقة سلبية مع مستوى الأجسام المضادة للروبيلا في المجموعتين ذات مغزى إحصائي وłużة إحصائي عند أصحابئ عند المجموعة الأولى بينما كان وزن الوليد له علاقة مزدوجة إحصائي عند الأطفال في المجموعة الثانية.

الاستنتاجات: ظهر أن وجود الأجسام المضادة بشكل موجب وعميق عند النساء وأطفالهن بعد العملية القيسارية كان أعلى من النساء بعد الولادة الطبيعية وأطفالهن، مع وجود علاقة سلبية بين الأجسام المضادة وعمر الأمهات، التعليم والكثافة السكانية.

كلمات المفتاح: الأجسام المضادة للروبيلا والأمهات بعد الولادة

معالجة انتكاس لحالة مصابية ببايضاض الدم النخاعي الحاد (من نوع لوكيميا الخلايا النخاعية الح단 - النوع الثالث) باستخدام مستنشن ثلاثي أوكسيد الزرنيخ
نبيل سليم مراد، وسام فاضل

الخلاصة

خللية الدراسة: ابيضاض الدم النخاعي الحاد أو لوكيميا الدم النخاعية الحادة (AML) يصيب أنواعًا من الدم حيث تنتشر الخلايا الأولى التي تتطور لتصبح الخلايا غير النشطة بكرات الدم البيضاء وتظهر ببعضهم كيمياء سرطانية قادرة على التناسل. أن هذا المرض هو من التعقيد بشكل يشمل تفرعات وأنواع متعددة تتطلب معالجات مختلفة تبعًا لنوع المرض وعناصره الأخرى.

عند اللوكيميا النخاعية ينشأ التشريعة عادةً بخلايا متشابهة إلى مدى نقص أغلب خلايا اللوكيميا بالدم النخاعي الحاد، فورًا وفوريًا يبدأ العلاج. عند الخلايا المتشابهة في الخلايا النخاعية الحادة، عندما تكون الخلايا الشاذة قاترة على النضج وتبقى غير بالغ، ويتم تشخيصها بشكل بسيط في حالة الخلايا الطبيعية. ويكون العلاج بالنفع. وهو لوكيميا الخلايا النخاعية الحادة (ويكي إد) من إحدى المراحل الأولية المباينة لعلاج أنواع الخلايا الحادة من الأنواع المبتكرة حيث يتوقف نمو الخلايا الدمية عندما يتحقق توازنها أو تشكيلها تعتمد بحالة الت çalışmaları أو الخلايا الطبيعية.

وعودة واستمرار تعدادات كربات الدم البيضاء إلى المستويات الطبيعية وخصائص الخلايا النخاعية لوحدها. وعمد وجود أية علامات سريرية. وفي حالات معينة تمكن الخلايا النخاعية من العودة إلى فعاليتها عند بعض الحالات المرضية، وتم علاجها بعديد العلاج الأولية، وهي مرحلة الرجوع أو التوانير (RECURRENT OR RELAPSE) أو مراحل أخرى.

تهدف المعالجات الوسيطة إلى مرحلة حصار لخلايا اللوكيميا والقضاء عليها. وهي مرحلة تحقيق الخلو ومن ثم تأتي مرحلة التقوية (INDUCTION OF REMISSION) وتلتقي بمرحلة الوقاية (CONSOLIDATION) والمحافظة (MIANTENANCE) والتي تميز غالبيتها في الدوافع الثلاثة من اللوكيميا، وتوجد الكثير من التوليفات العلاجية المختلفة المستخدمة في كل من هذه المراحل العلاجية، باستخدام مجموع الم袼 الفعالات الكيميائية المتماثلة بالخصائص من منظمات أو لوكيميا التفاح.
مركبات ثلاثي أوكسيد الزرنيخ (ARSENIC TRIOXIDE-ATO) من قبل علماء الصين لأول مرة، من أجل استخدامها في معالجة النوع الثالث من اللوكيميا الخلايا الخبيثة والحادة بالخصوص في مئة حالات انتكاسة أو الارتداد بالإصابات وقد أثبتت البحوث العلمية المتدرجة والحالات المسجلة باستخدام هذا العلاج نجاحاً ملحوظاً في السيطرة على هذه الأنواع من اللوكيميا والتي جعلتها تصنف من الفئات ذات التجاوب الجيد للعلاج من حيث التكهن (PROGNOSIS).

في مستشفى الكاظمية التعليمي تم تسجيل الحالة الانتشار في هذا التقرير كونها أول حالة مسجلة في العراق تستخدم مركب (ATO) لمعالجة مريضة في الواحد والثلاثين من عمرها أصبحت بحالة الانتكاس في لوكيميا الخلايا النخاعية الخبيثة للمرة الثانية خلال عامين وكانت قد علقت سابقاً بالعقاقير الكيميائية مع مركب الأترا (ATRA) فقط، بجرعة تعدل 15 ملغ/يوم، وقصرت العلاج حتى اليوم الرابع والأربعون وعندما سجلت حالة الخضوع أو الخلو للخلايا الورمية ليتبعتها كورسات التنوية العلاجية وقد تضمنت أيضاً إلى العقاقير الكيميائية بنفس الجرعة خمسة أيام في الأسبوع لمدة 3 أسابيع، ومن ثم تم الاستمرار بمعالجة المريضة بإعطائها مركب الإترا كل 3 أسابيع لمدة 15 يوم وعقار الميثوتريكسيت أسبوعياً. عقار الميركابوتوبيرين يومياً ولا زالت المريضة تحت المتابعة حتى وقت كتابة هذا التقرير.
